Leading

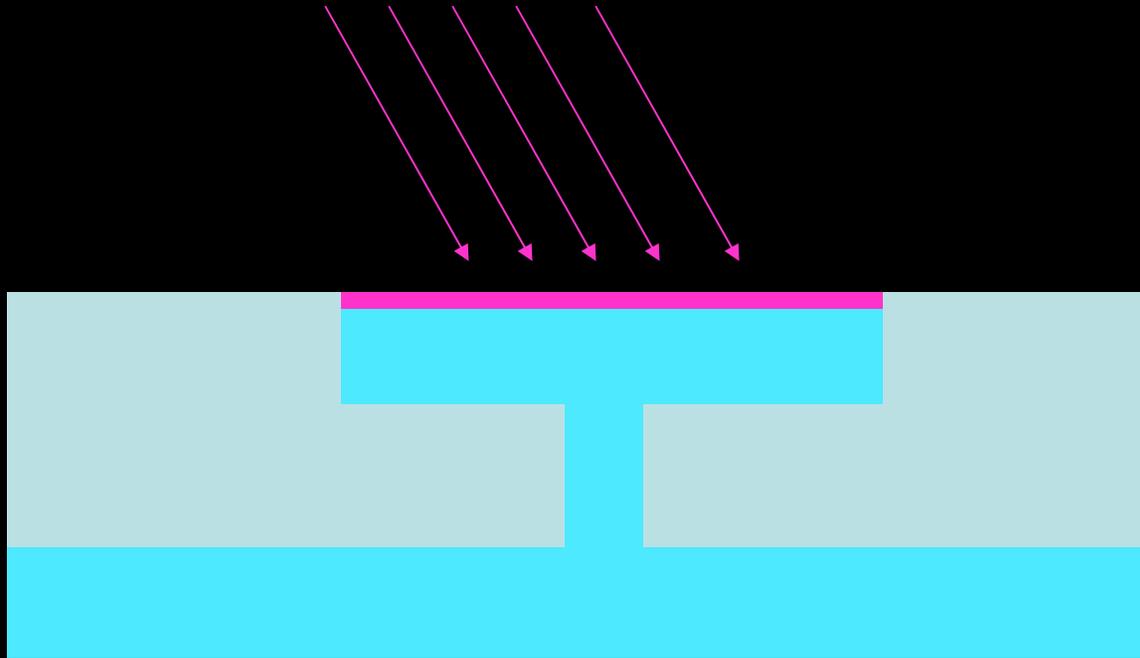

Surface Modification Processes

1. Emplacement

Endogenic material placed at the surface by geologic processes

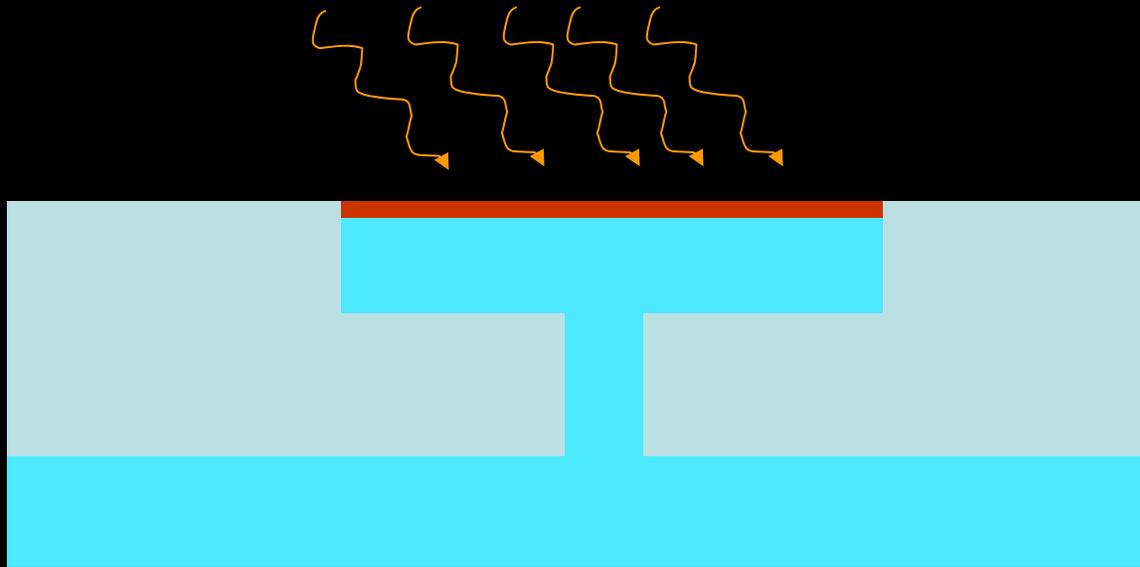

Surface Modification Processes

2. Implantation

Ions (H, Na, K, Cl, S, O... Mg?) implanted into the surface ice

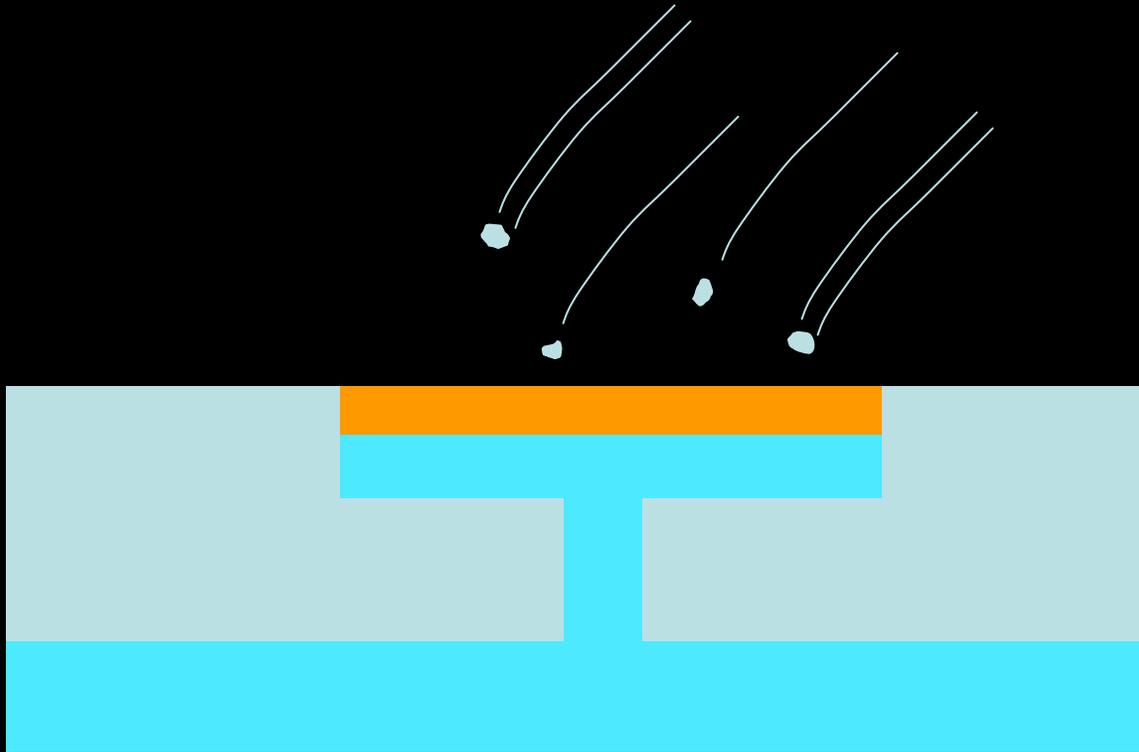

Surface Modification Processes

3. Radiolysis and photolysis

Radiation-driven chemistry alters surface composition

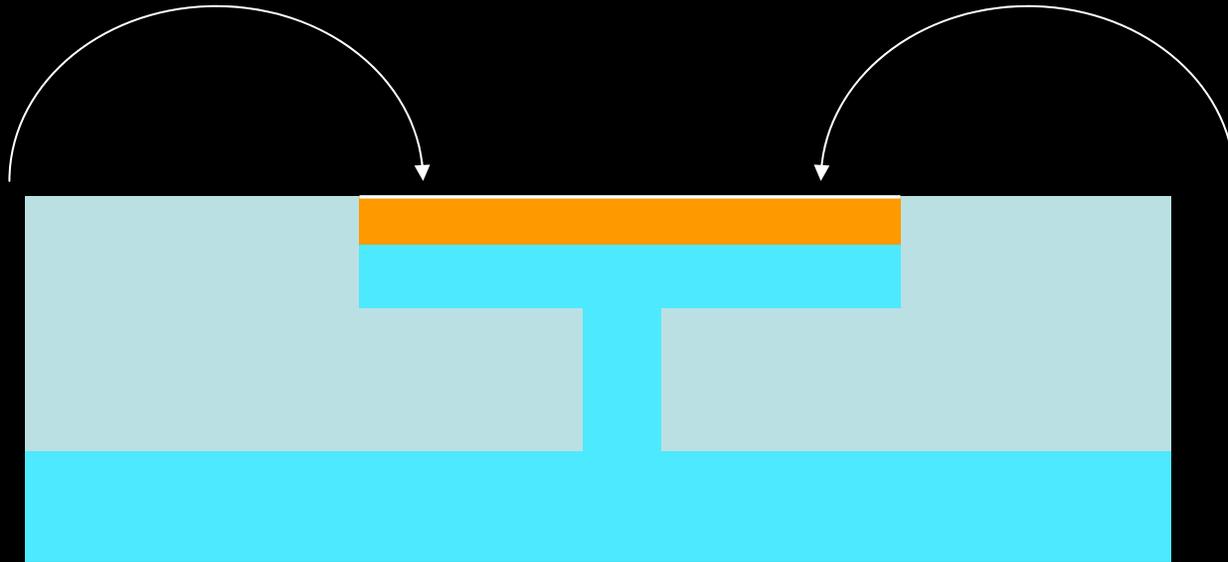

Surface Modification Processes

4. Impact Gardening

Micrometeoritic bombardment mixes the upper ~1-2 m

Surface Modification Processes

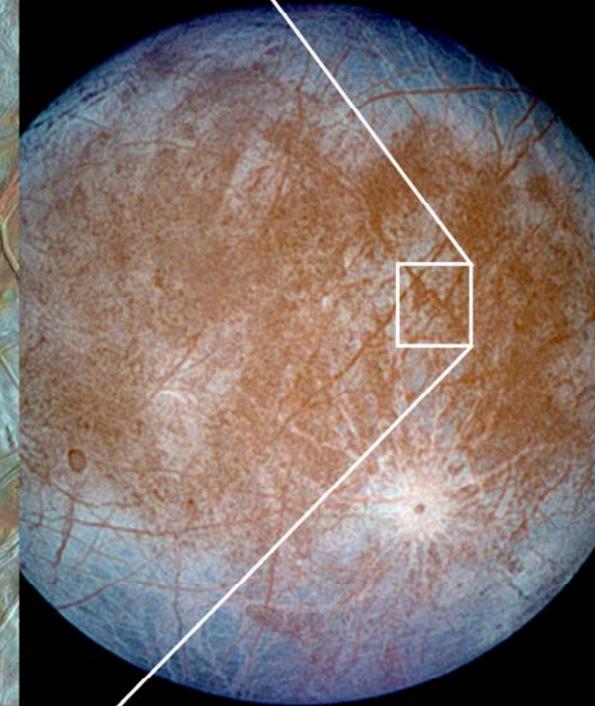

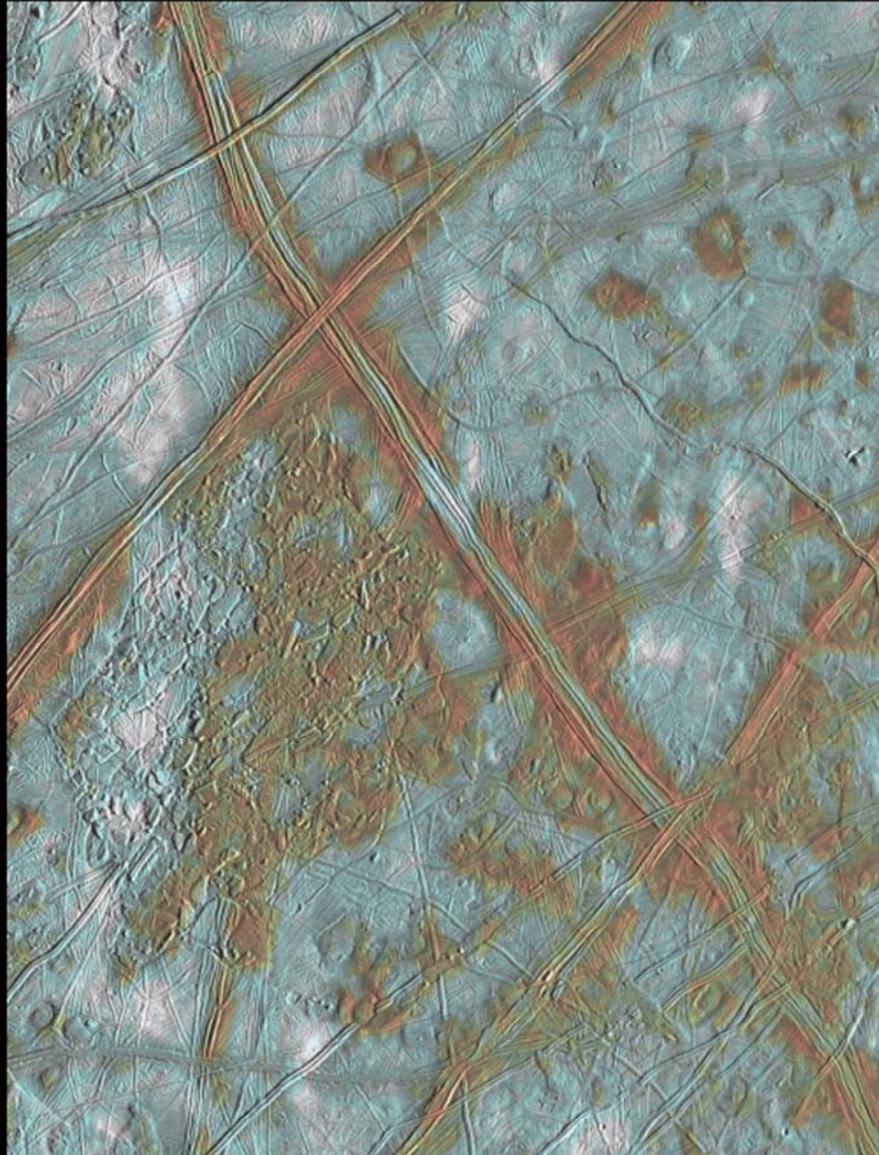

5. Frost (re-)Deposition

Linea brighten over time as water ice is vapor-deposited on surface

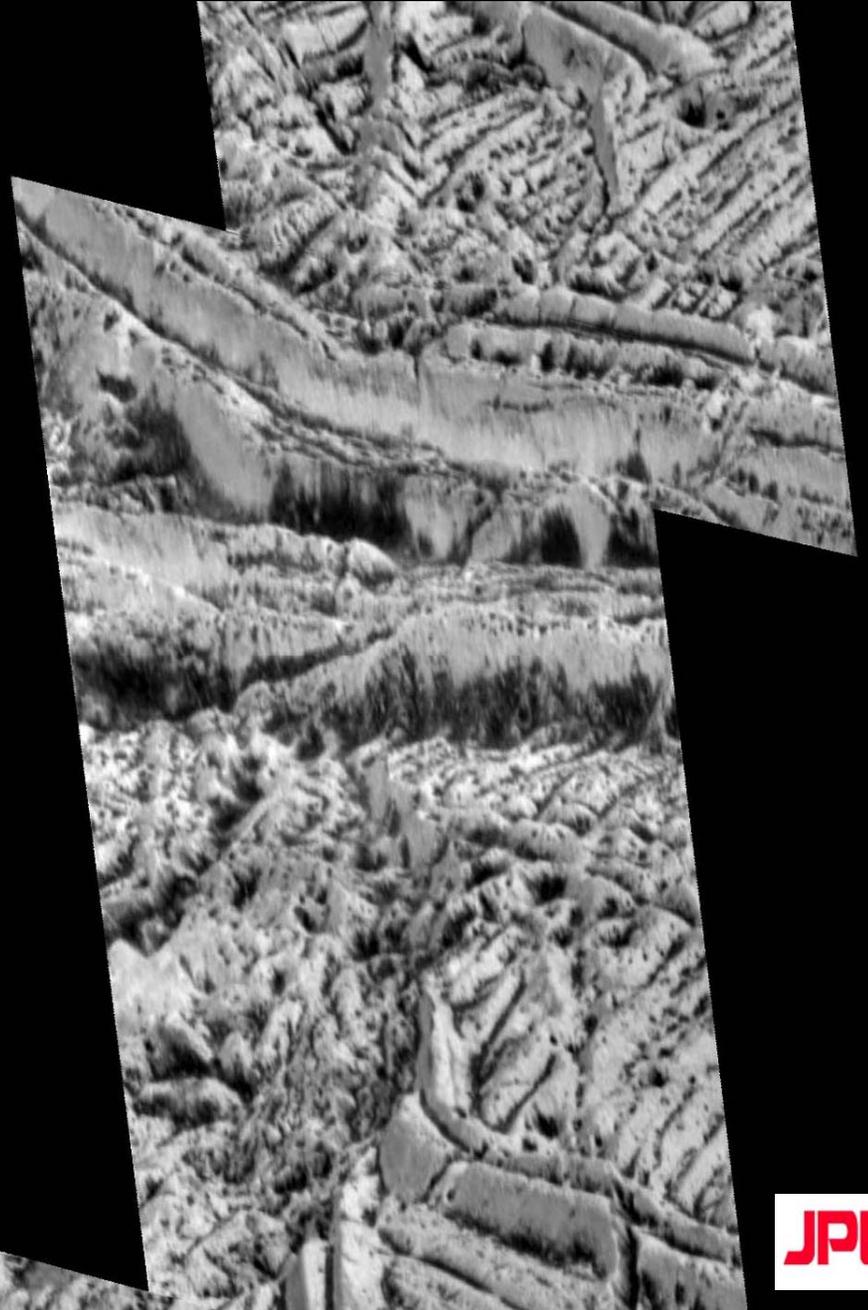

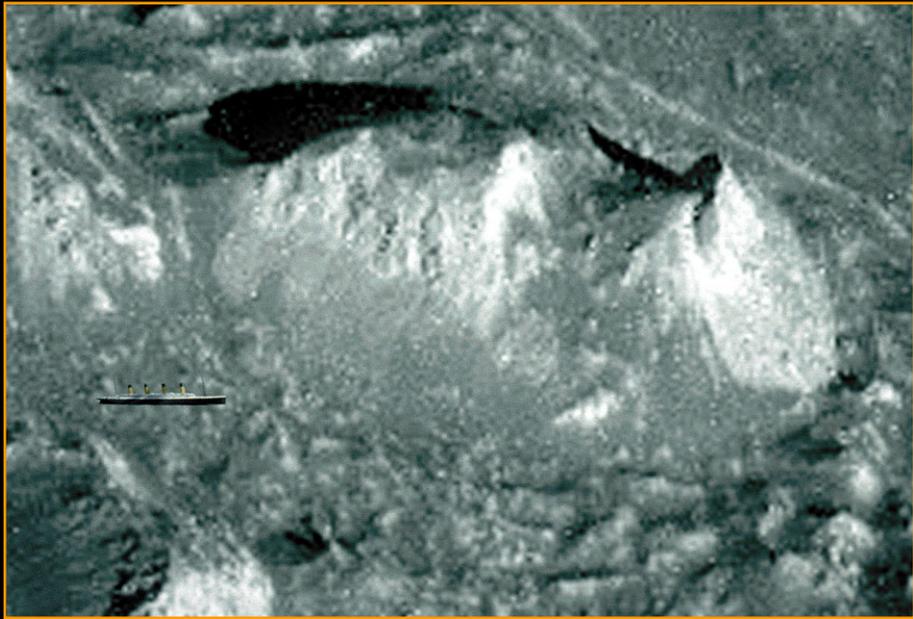

Surface Modification Processes

Material emplaced at the surface has been modified by radiation, impact gardening, and the re-deposition of sputtered and/or excavated frost

Europa Surface Character

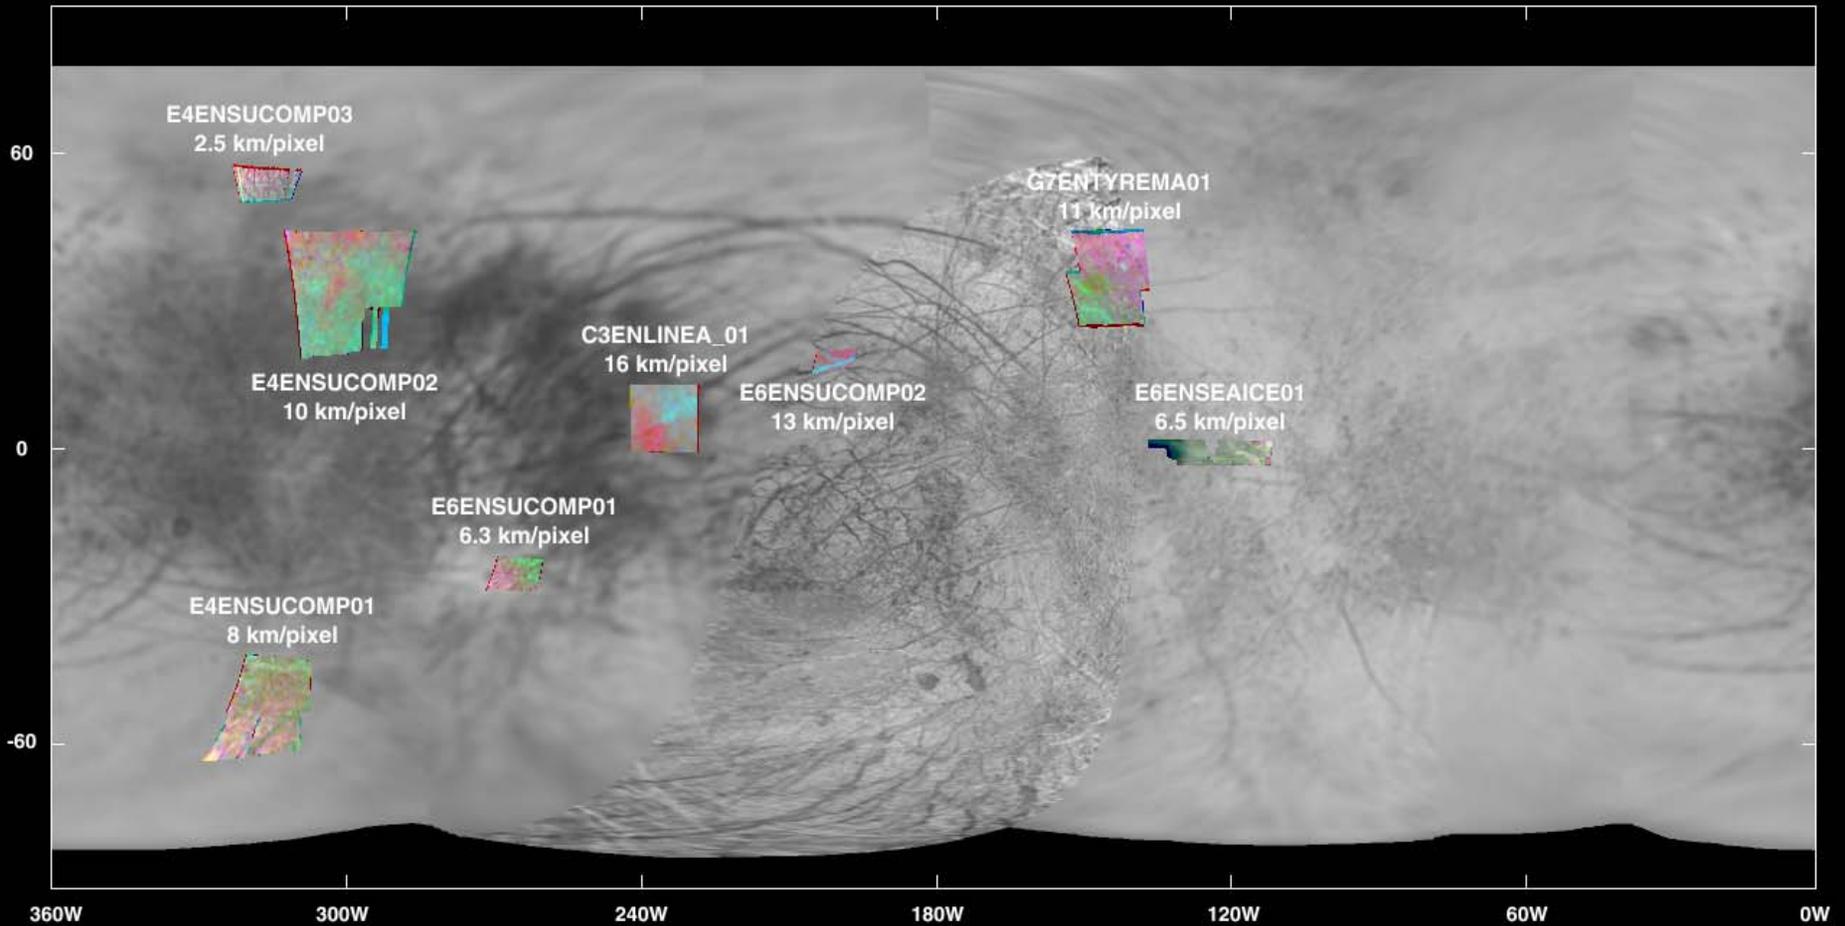

- Highly variable surface topography
Typical ~100-300m
Up to > 1250 m
- Many scarps and vertical cliffs
- Ridges of ~30-35 degree slope
- Exposed faces
- Lag deposits

NIMS Europa High Resolution Coverage

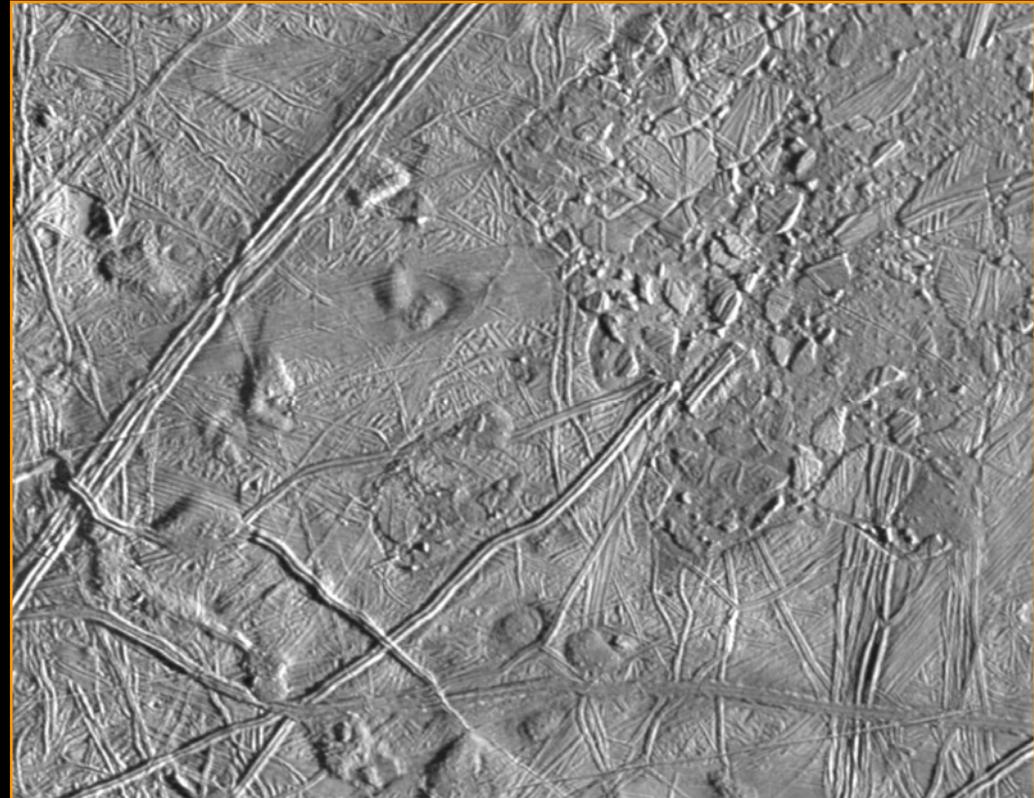

Surface Composition of Europa

Known:

- Water Ice
- Carbon Dioxide Ice
- Sulfur Dioxide Ice
- Hydrogen Peroxide
- Hydronium Ion (H_3O^+)

Expected:

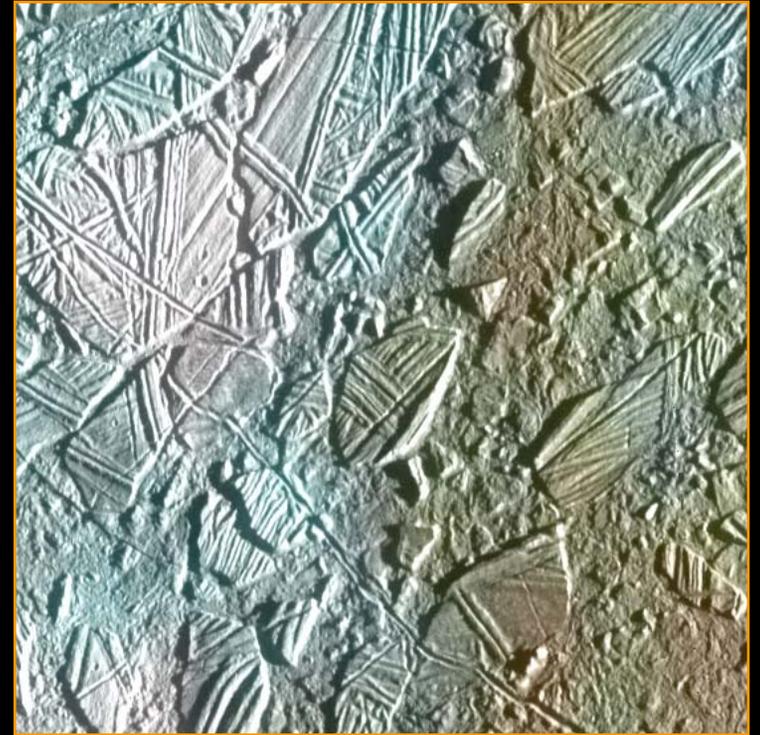

- Hydrogen sulfide (H_2S)
- Formaldehyde (H_2CO)
- Hydrochloric Acid (HCl)
- Carbon Monoxide (CO)
- Oxygen (O_2), Ozone (O_3)

Surface Composition of Europa

“Non-Ice” Material:

- Sulfuric Acid Hydrate
- Hydrated Sulfate Salts
- Irradiated Material
- Organic Material?
- Clathrate Hydrates?

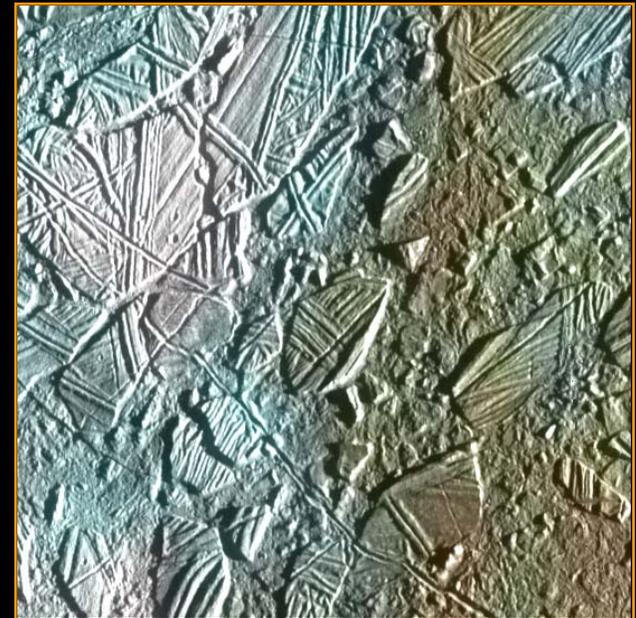

Hydrated Sulfur Compounds

Magnesium Sulfate Hydrates

$\text{MgSO}_4 \cdot 1\text{H}_2\text{O}$	Kieserite
$\text{MgSO}_4 \cdot 2\text{H}_2\text{O}$	Sanderite
$\text{MgSO}_4 \cdot 4\text{H}_2\text{O}$	Starkeyite
$\text{MgSO}_4 \cdot 5\text{H}_2\text{O}$	Pentahydrate
$\text{MgSO}_4 \cdot 6\text{H}_2\text{O}$	Hexahydrate
$\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$	Epsomite
$\text{MgSO}_4 \cdot 11\text{H}_2\text{O}$	Undecahydrate

Sodium Sulfate Hydrates

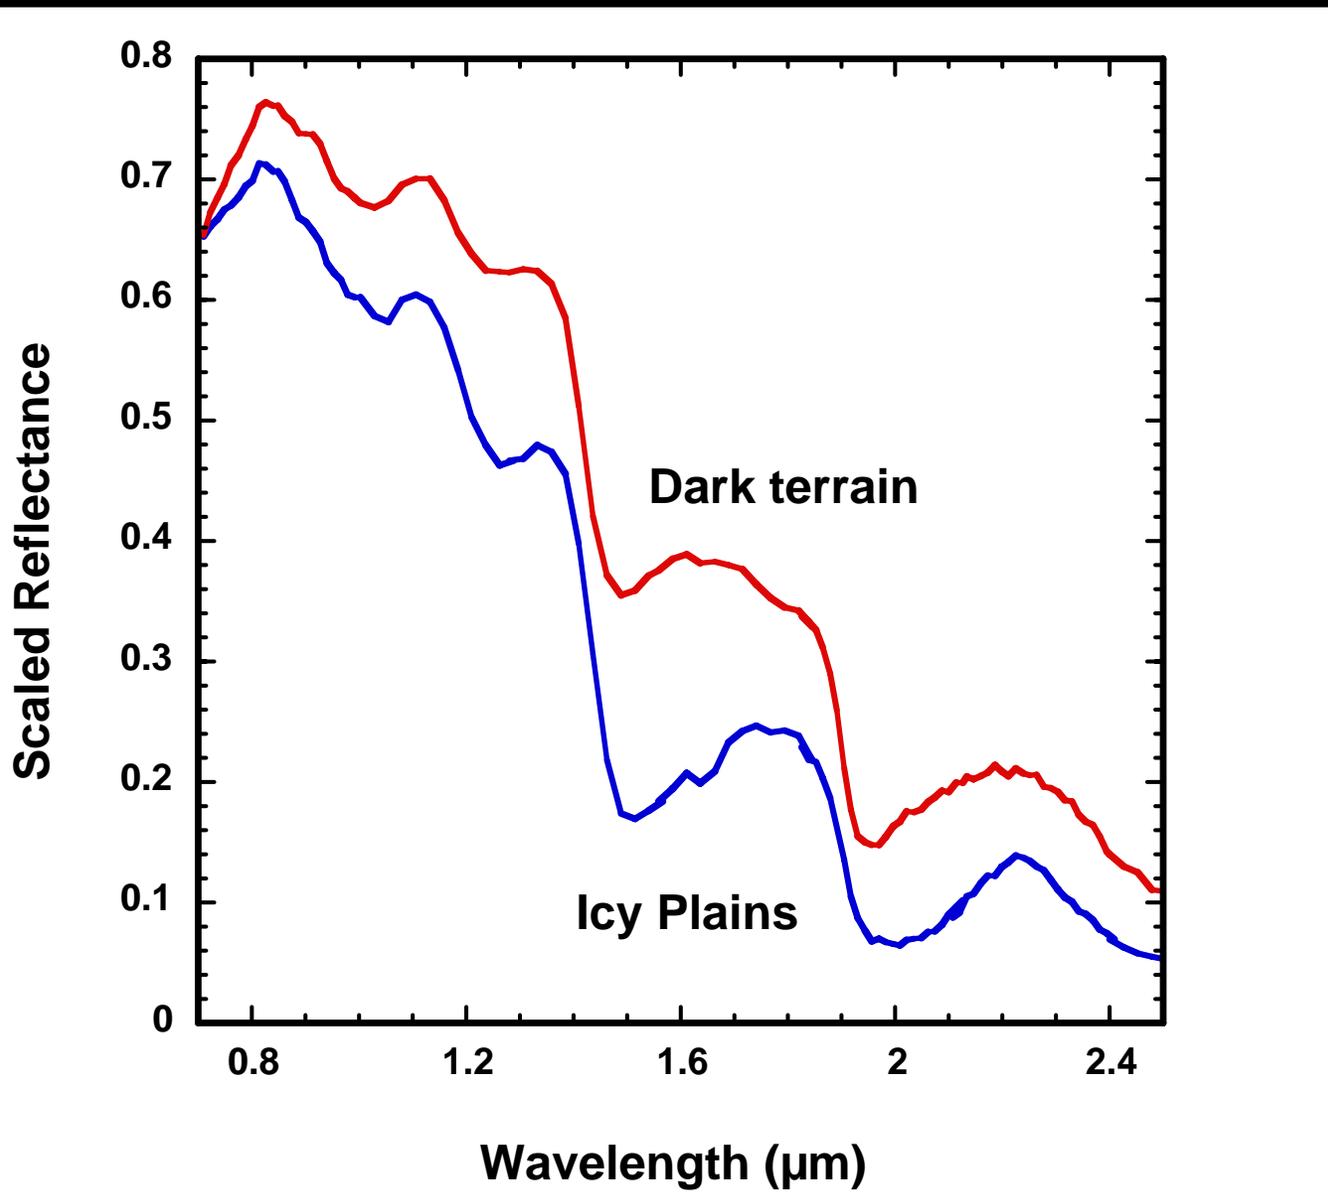

$\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$	Mirabilite
$\text{Na}_2\text{Mg}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$	Bloedite

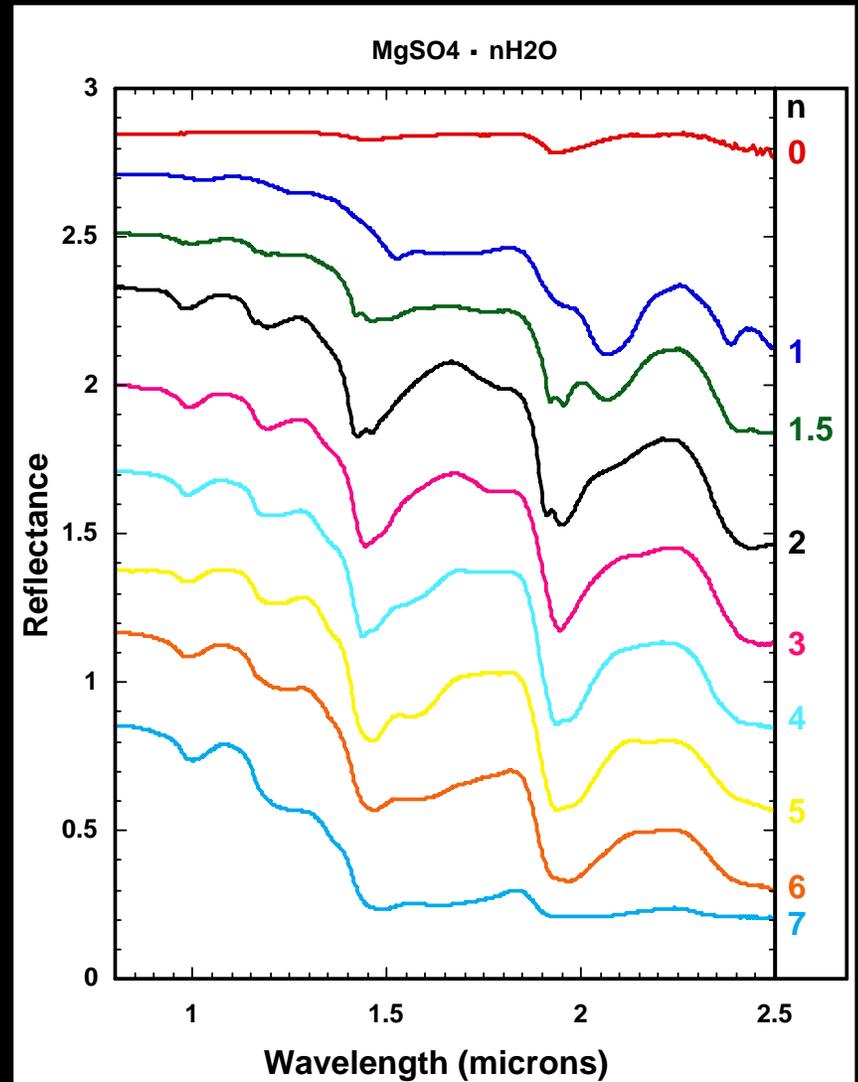

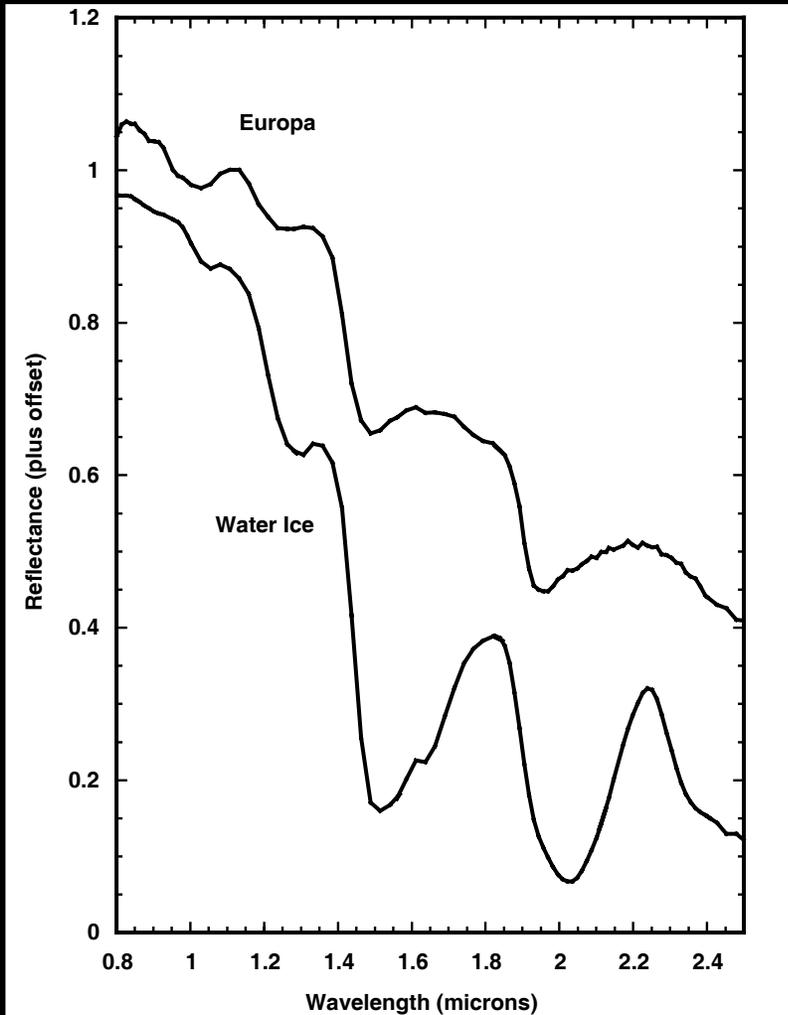

Other Sulfur Compounds

$\text{Na}_2\text{S} \cdot 9\text{H}_2\text{O}$	Sodium Sulfide Nonahydrate
$\text{H}_2\text{SO}_4 \cdot 8\text{H}_2\text{O}$	Sulfuric Acid Hydrate
$\text{MgSO}_4 + \text{H}_2\text{O}(l)$	Magnesium Sulfate Brine

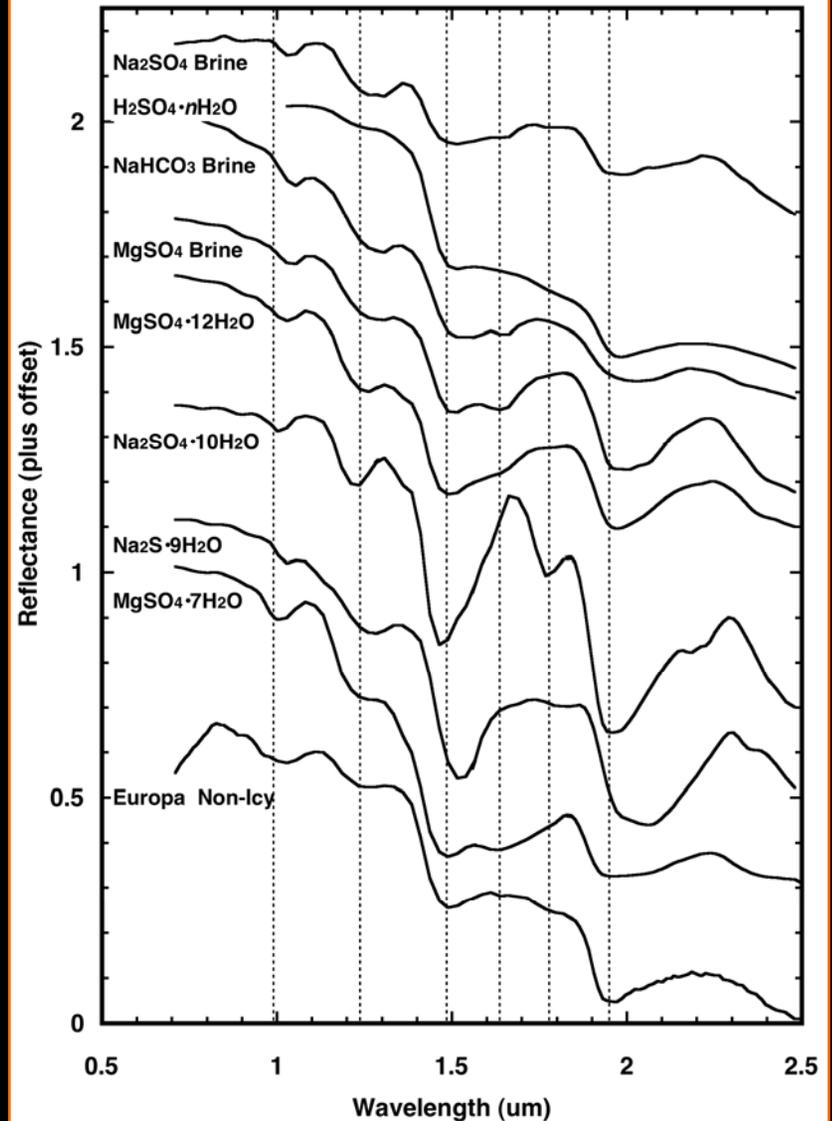

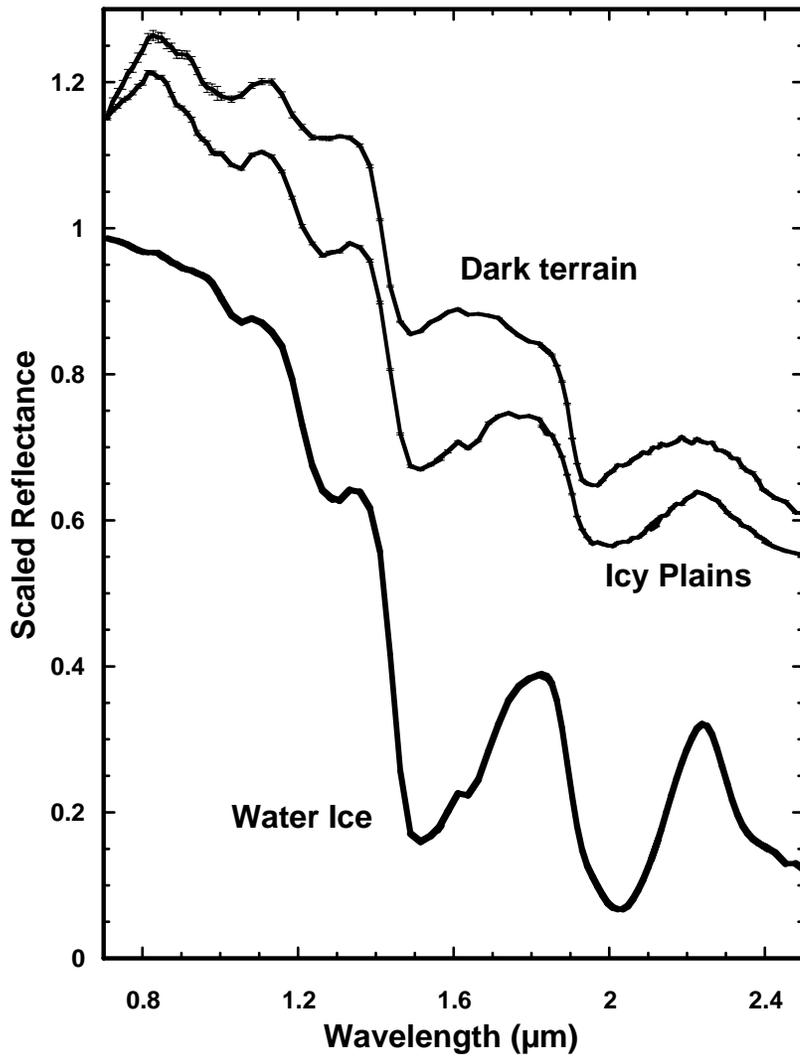

Galileo NIMS spectroscopy of European surface units

Spectral Effects: Water of Hydration

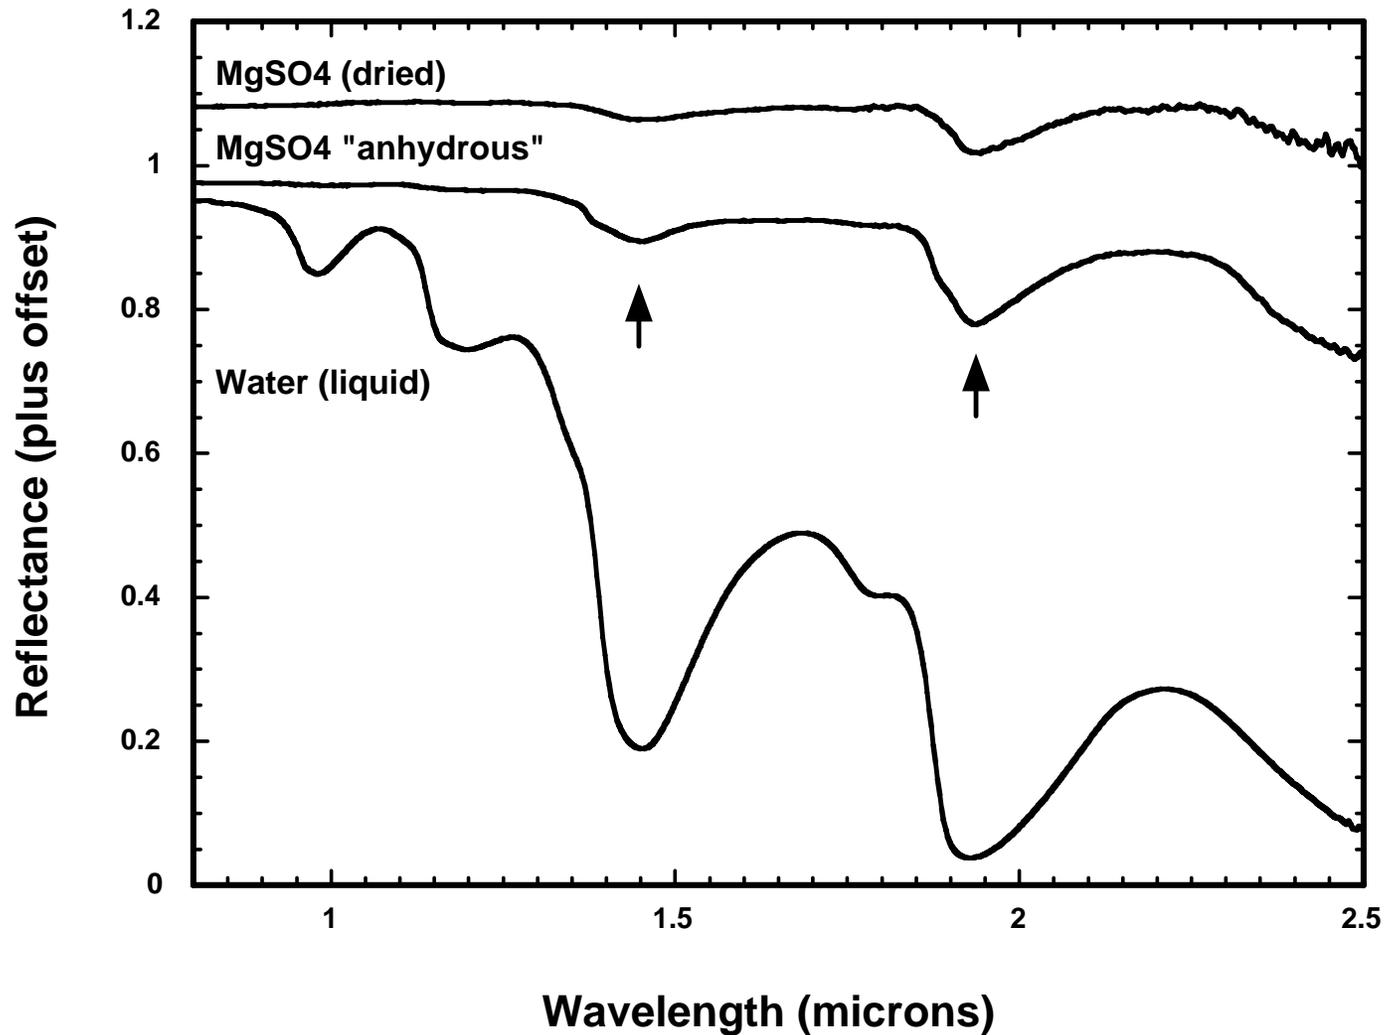

Europa Spectrum and Hydrated Materials

Hydrated sulfates all exhibit Europa-like spectral characteristics

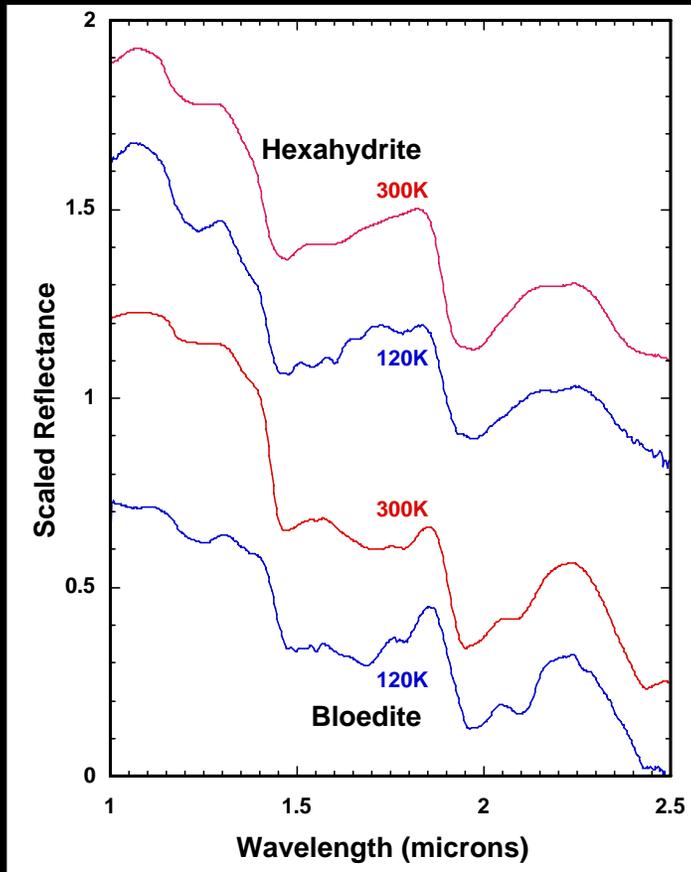

Spectral Effects: Water of Hydration

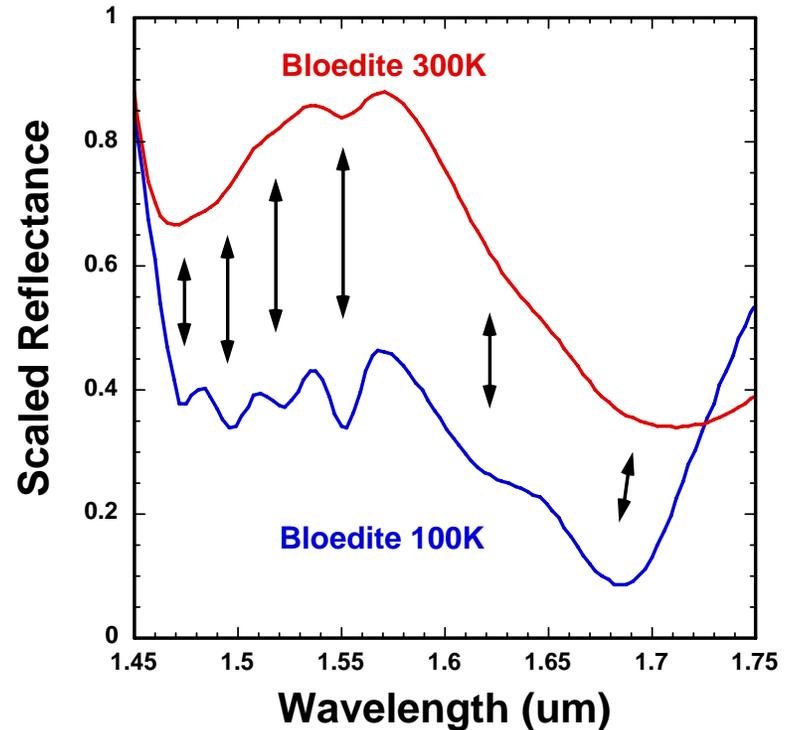

These absorptions are *not* intrinsic to the host molecule!

Temperature-dependent Effects

Hexahydrate ($\text{MgSO}_4 \cdot 6\text{H}_2\text{O}$)
and Bloedite ($\text{MgNa}_2(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$)
suggested to comprise 80% of surface
material (McCord et al., 1999)

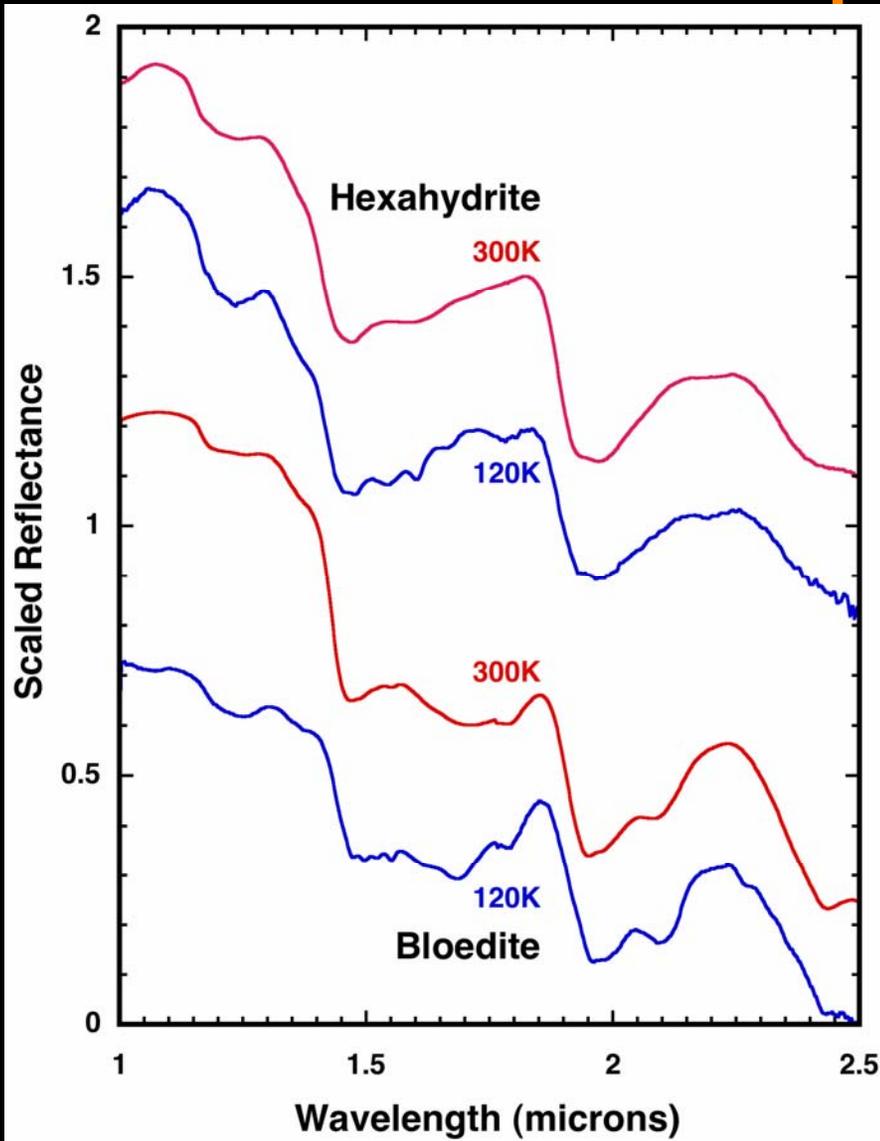

Separation of Water Features in Hydrates

BUT... Spectral behavior at cryogenic temperatures may differ markedly from that at room temperature (Dalton and Clark, 1999; Dalton, 2000, 2003, 2005)

Temperature Dependence of Spectral Properties

Hexahydrite ($\text{MgSO}_4 \cdot 6\text{H}_2\text{O}$) and Bloedite ($\text{MgNa}_2(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$) suggested to comprise >70% of surface

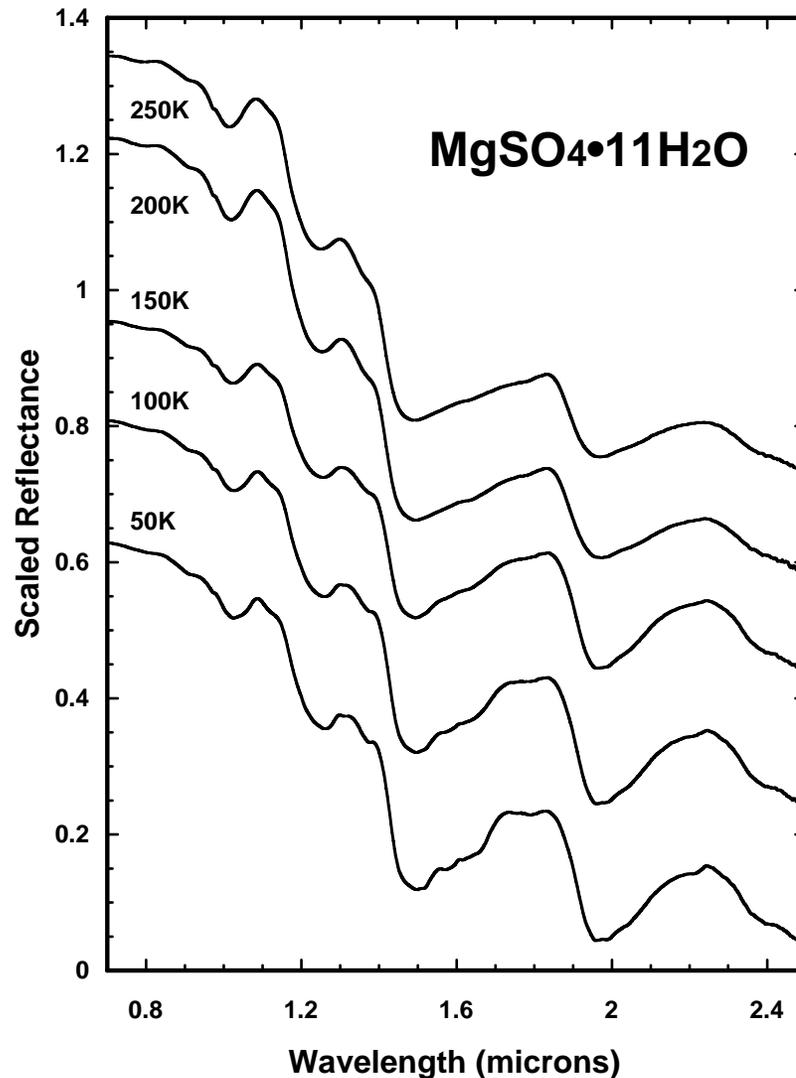

material (McCord *et al.*, 1999) based on available room temperature spectra

Subsequent cryogenic spectra (eg., Dalton *et al.*, 2000, 2003, 2005) demonstrated strong temperature dependence of spectral absorption band strengths, shapes, positions

Spectral models utilizing cryogenic spectroscopy thus have the potential to provide realistic constraints on surface composition of icy satellites

Magnesium Sulfate Undecahydrate

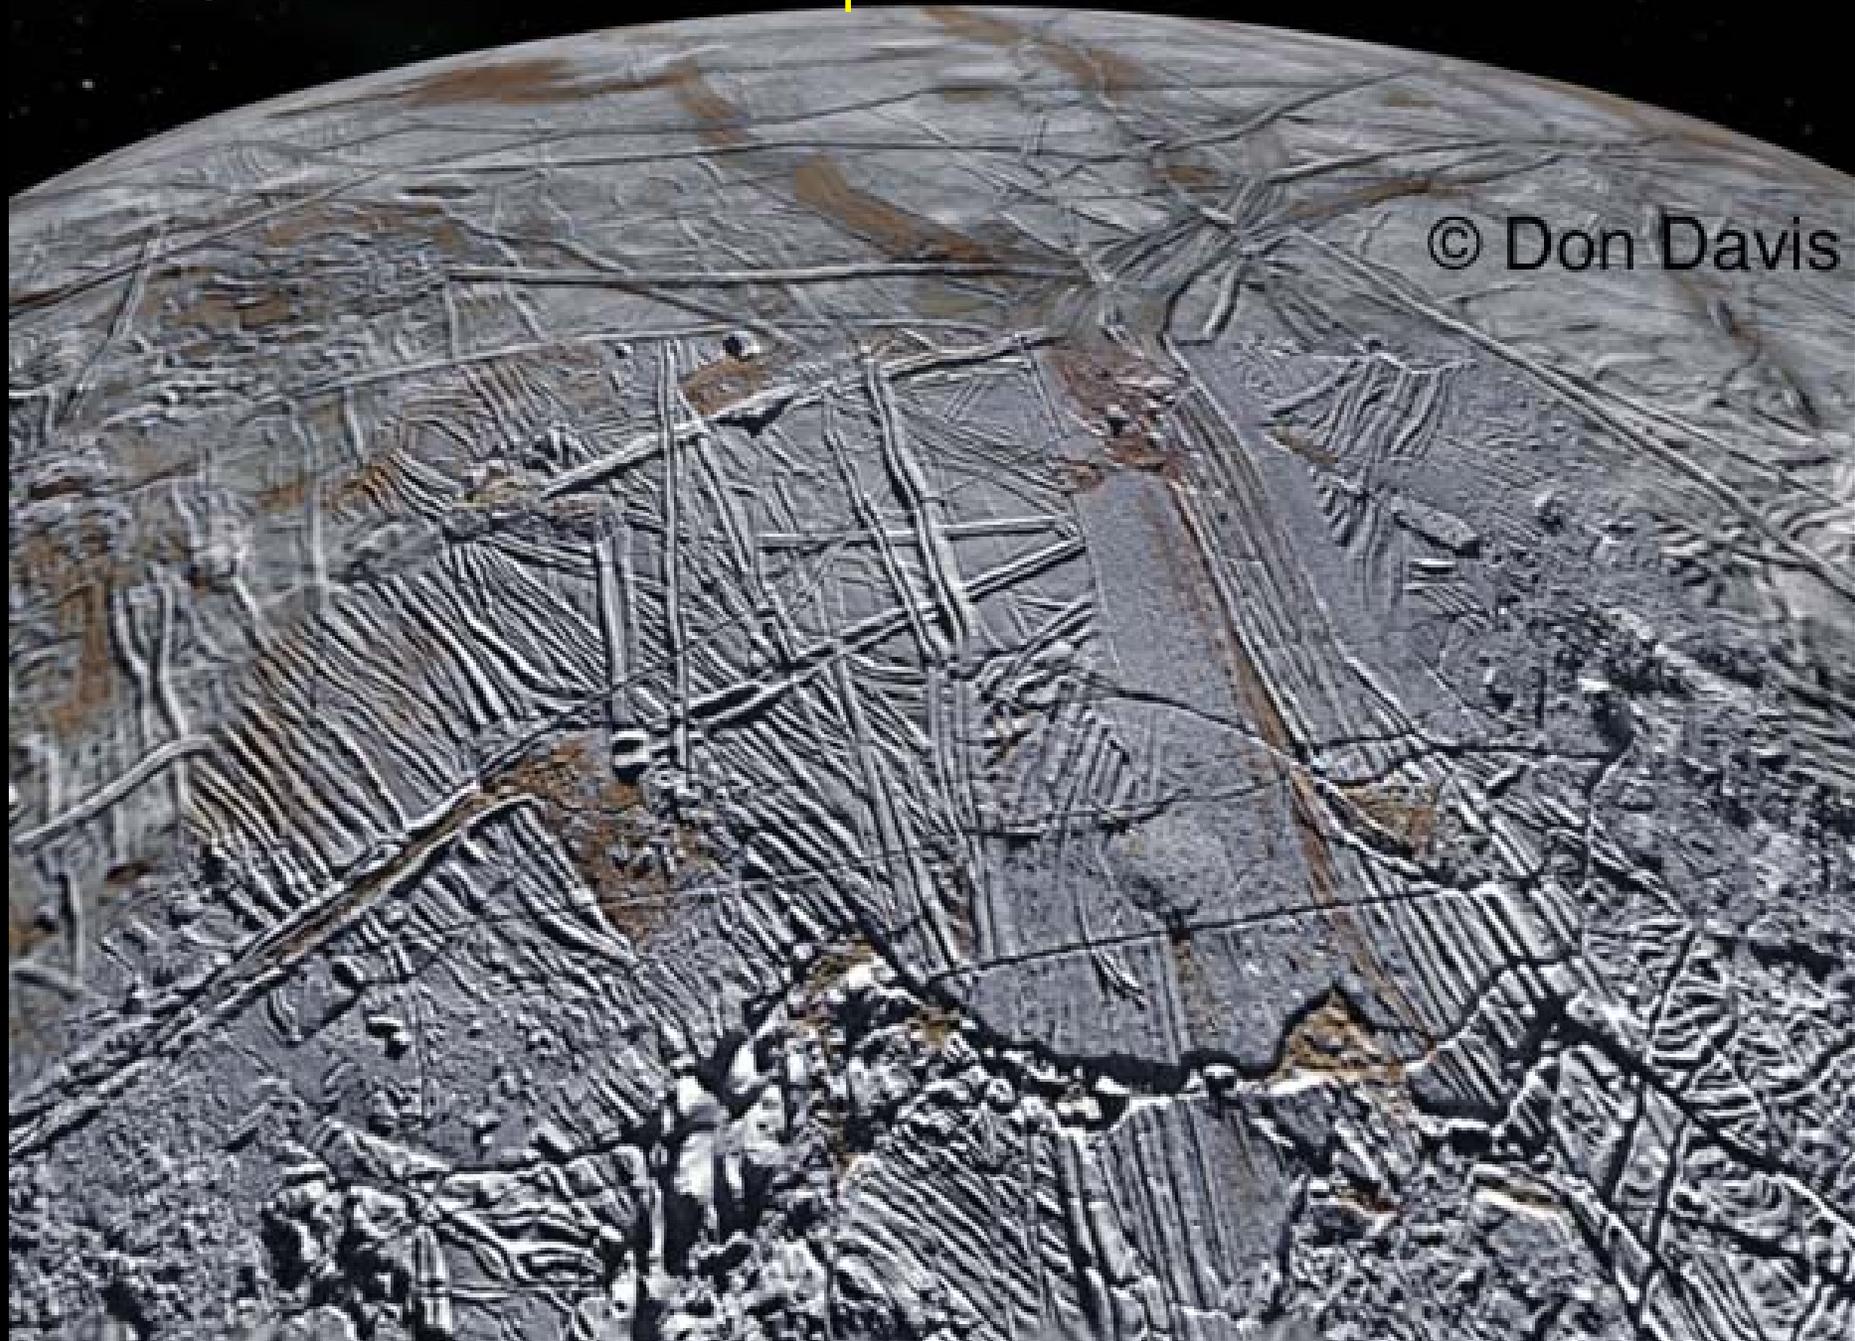

As temperature is reduced below 200K, individual absorption features separate and narrow, producing fine structure that can be used to discriminate between materials

Dalton et al., 2005

- Life contains hydrates
- Life contains amides

Some Popular Hydrated Materials

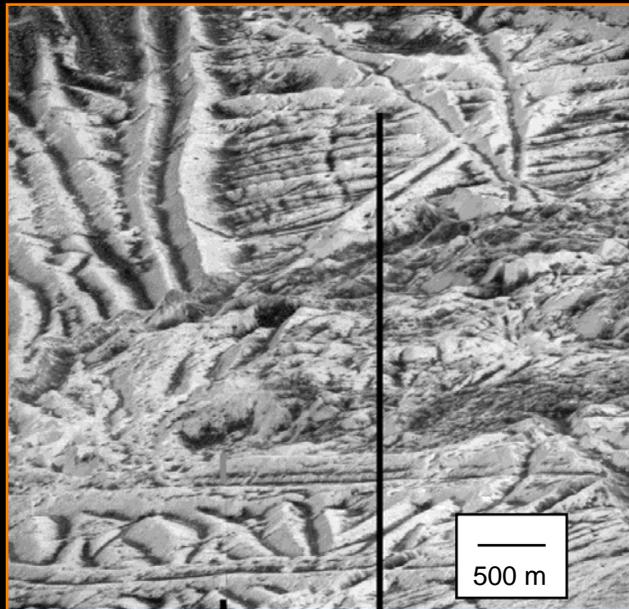

Spatial Considerations for Interpretation of Surface Composition

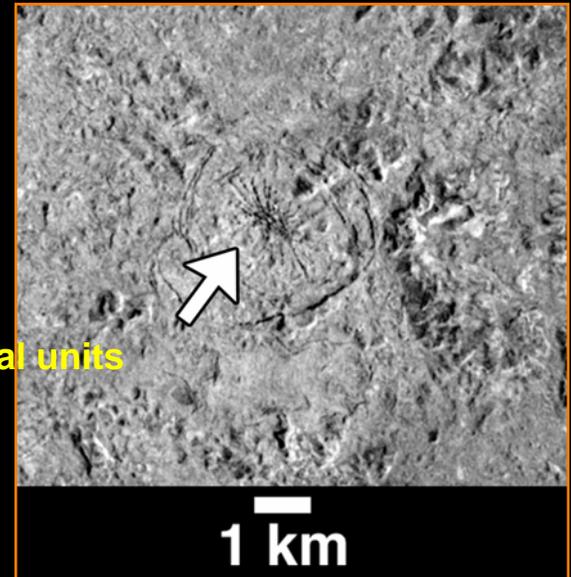

Discrimination of surface constituents requires high spectral AND high spatial resolution

Surface heterogeneous at small spatial scales
Spectra are mixtures of adjacent surface units
∴ large footprint reduces detectability of constituents

Identification of surface materials requires spectral imaging of individual units

Galileo SSI image of ridged plains at 6 m/pixel. Linear troughs containing dark material are about 100 m wide.

Galileo SSI image of unique crater with apparent subsurface material flowing onto surface from radial fractures.

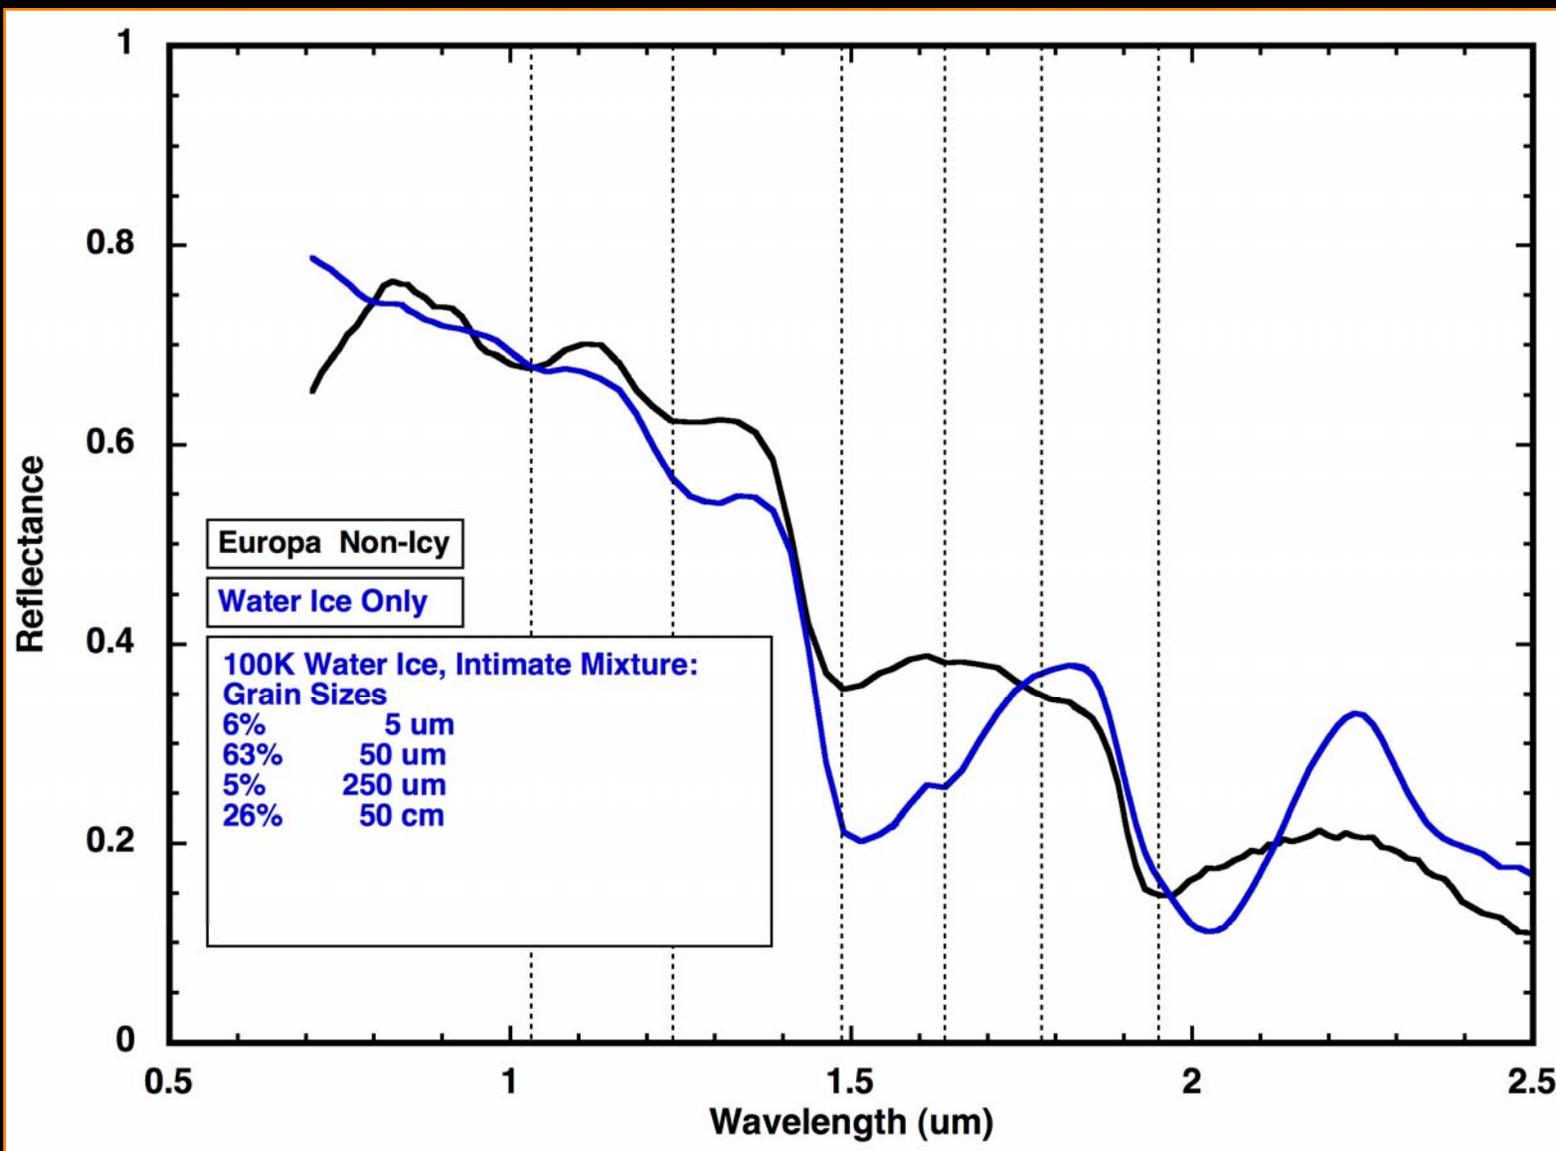

Spatial Resolution:

Surface heterogeneous at 25 - 100 m scales

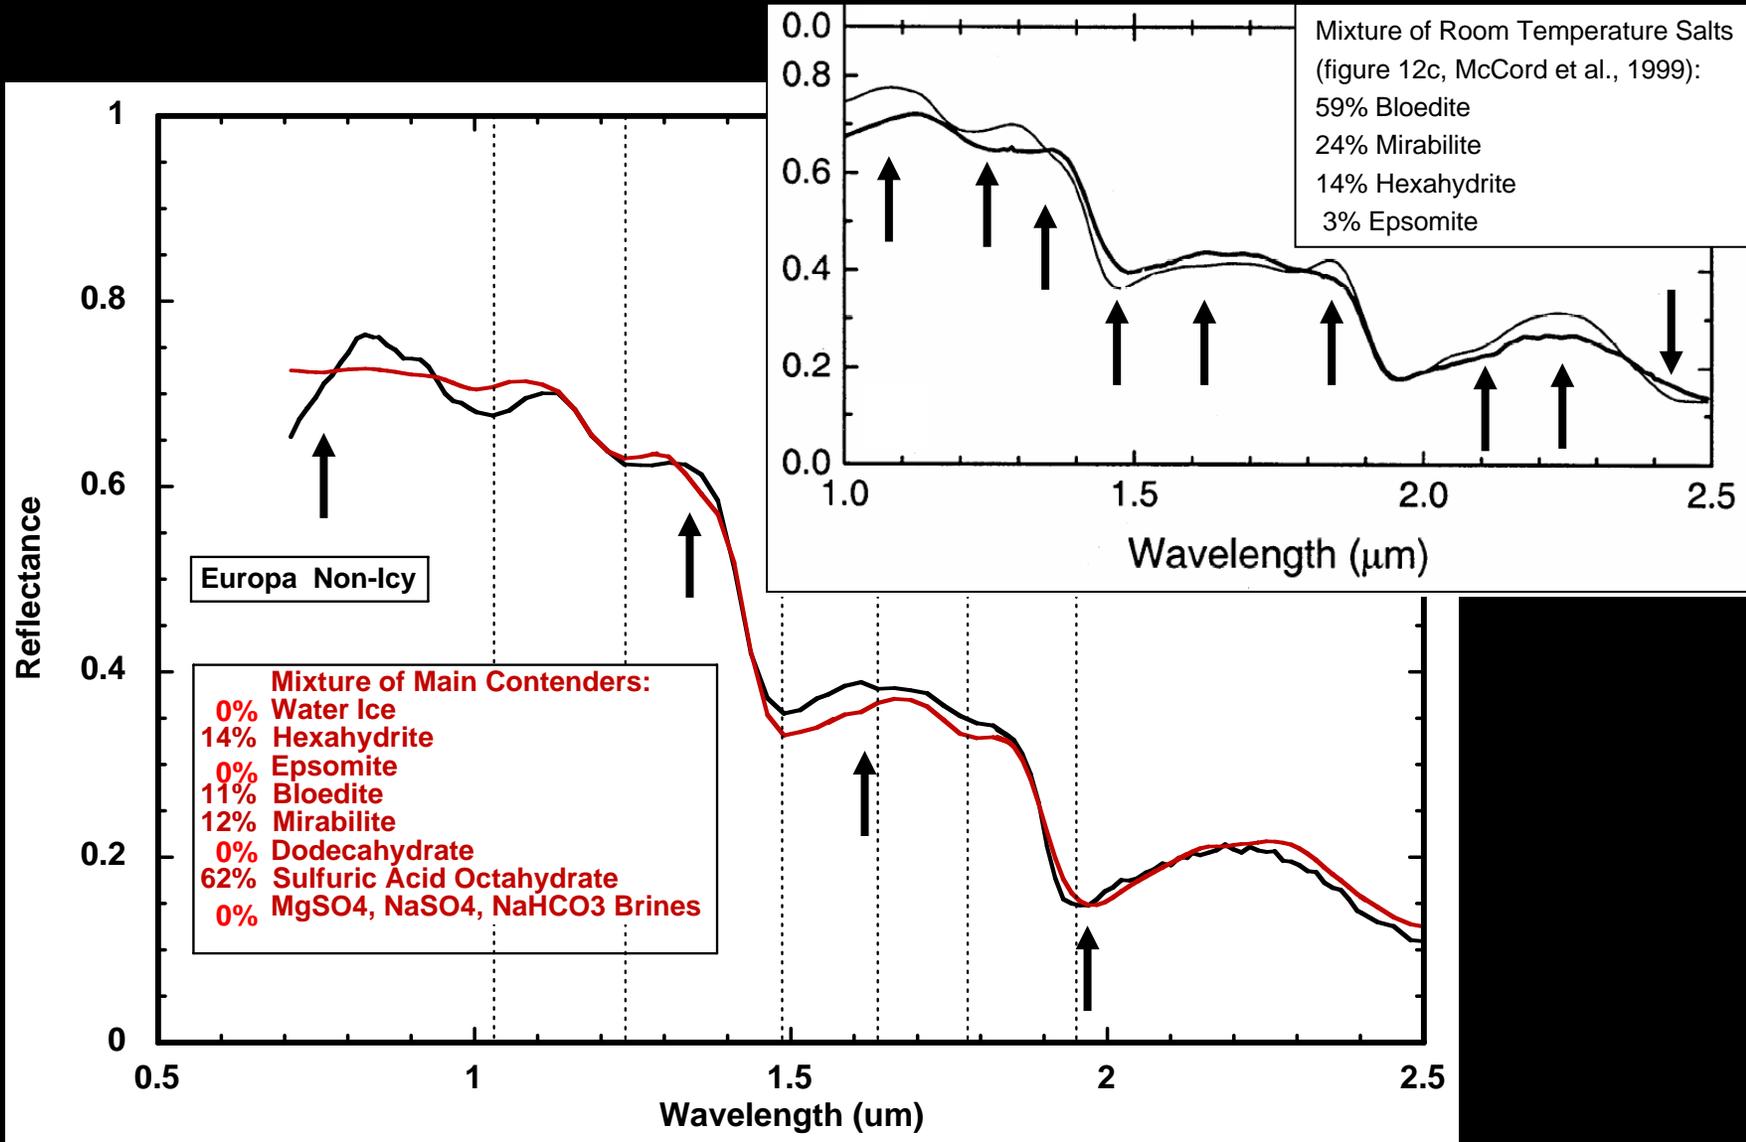

Signal to Noise:

Sampling statistics and radiation noise require multiple pixels across contiguous surface units

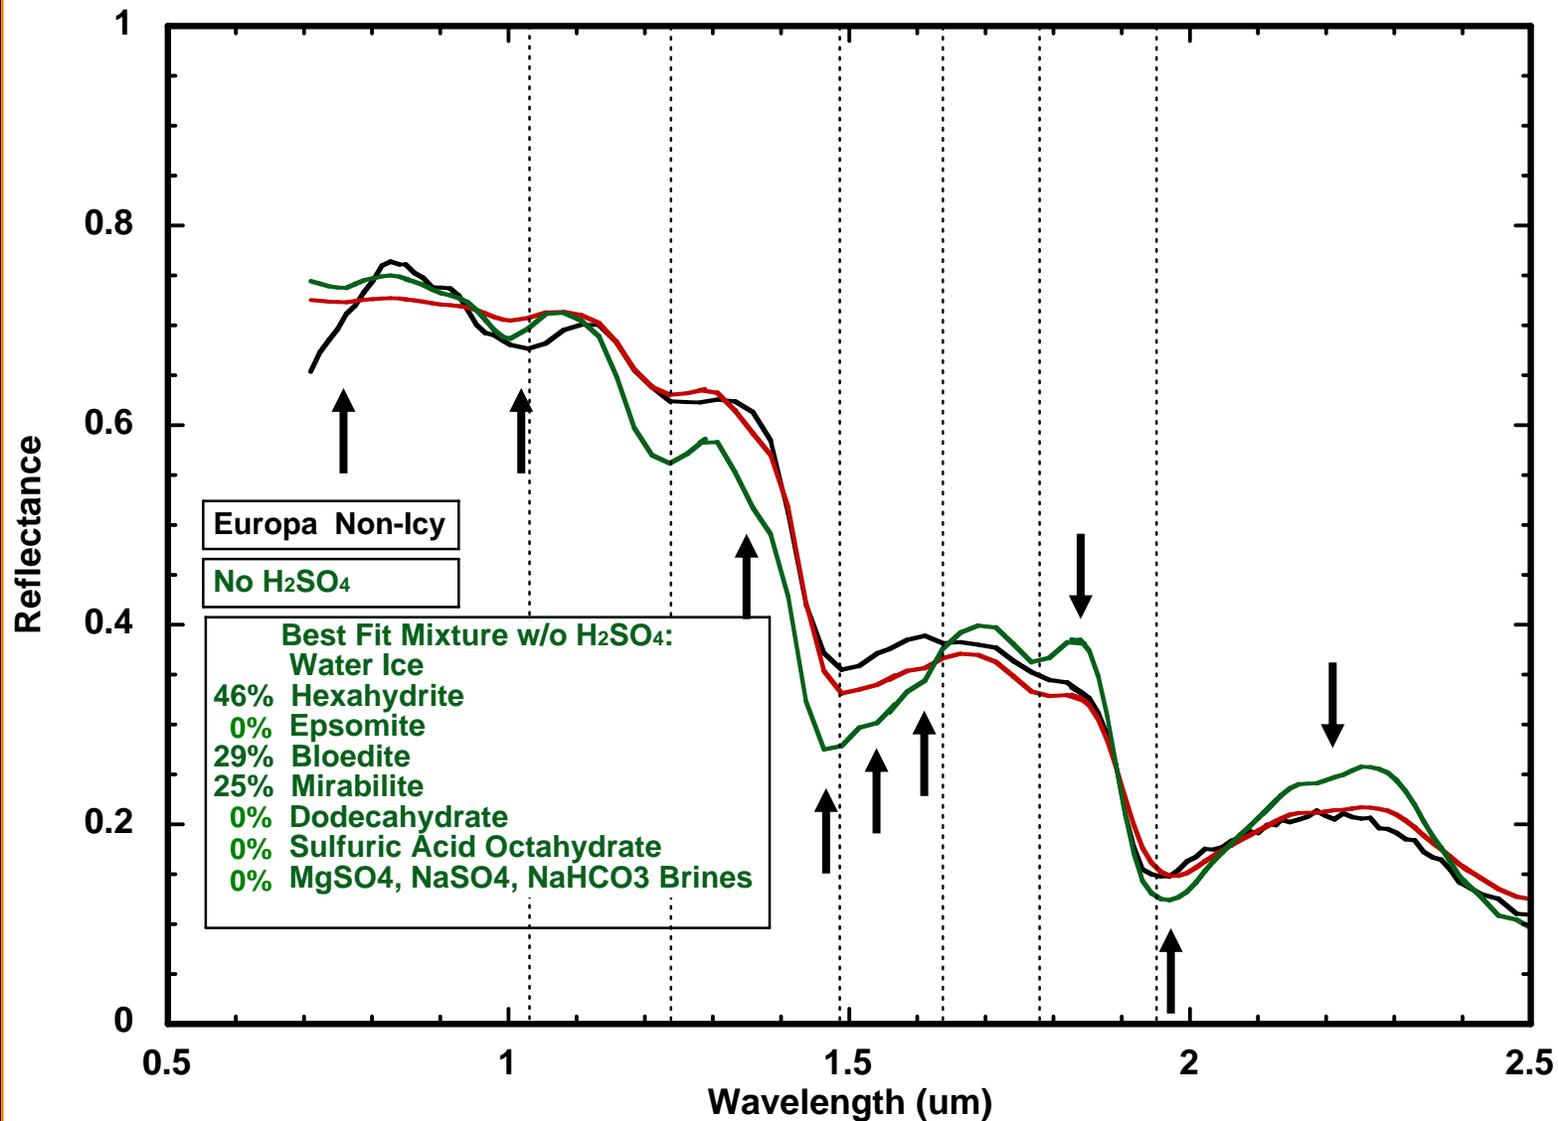

Fit to Europa "Non-Icy" Spectrum

Fit to Europa "Non-Icy" Spectrum

Fit to Europa "Non-Icy" Spectrum

Galileo SSI Observation at 9 m/pixel

Future investigations such as a Europa Flagship Mission may shed light on these mysteries...given sufficient spatial and spectral resolution, and the availability of relevant laboratory data.

Conclusions:

- **Highly hydrated sulfate salts exhibit more Europa-like spectral behavior than those of lower hydration states.**
- **Best spectral models include BOTH hydrated salts and hydrated sulfuric acid.**
- **Fine structure at low temperatures can be exploited to discriminate between candidate materials.**
- **Lab spectra are needed for all candidate surface compounds.**

Conclusions:

- **Detritus of emplaced organisms is consistent with the observed spectral signature.**
- **Microbes are capable of surviving the low surface temperatures at Europa.**
- **Consideration should be given to a landed package that can confirm the presence of sulfate salts and acids, as well as search for evidence of biologically-derived material in the near subsurface.**
- **It is important to “look before we leap” in determining landing sites.**

Recommendations:

- The extreme surface roughness, and character of the upper surface layers need to be considered in developing a lander concept.
- Unraveling surface composition requires a concerted, collaborative effort that includes laboratory simulations.
- A lander must be prepared to encounter sulfuric acid, hydrogen peroxide, and a variety of salts.
- Access to the subsurface has the *potential* to acquire direct evidence of past or even recent biological activity.
