

Mapping land cover and insect outbreaks at test sites in East Siberia

V.I. Kharuk
V. N. Sukachev Institute of Forest,
Krasnoyarsk, Russia

Insect outbreaks are one of the primary factors of Siberian forests dynamics, determining species composition and carbon balance.

This table lists the main insect species which caused outbreaks in Siberian taiga

	Insect species	Main food source tree species	Max. outbreak area, thousand hectares
1.	<i>Dendrolimus superans sibiricus</i> Tschetw.*	fir, pine, larch, spruce	> 1000
2.	<i>Lymantria dispar</i> *	larch, broadleaf	300
3.	<i>Orgyia antiqua</i>	larch, birch	40
4.	<i>Dasychira abietis</i>	spruce, fir, pine, larch	1000
5.	<i>Leucoma salicis</i> *	aspen, willow	100
6.	<i>Lymantria monacha</i> *	pine, spruce	5
7.	<i>Ectropis bistortata</i> *	spruce	400
8.	<i>Bupalus piniarius</i> *	pine	50
9.	<i>Semiothisa signaria</i> *	spruce, fir	10
10.	<i>Simiothisa continuaria</i>	larch	5
11.	<i>Erranis jacobsoni</i> *	larch	50
12.	<i>Biston betularius</i>	birch	50
13.	<i>Phalera bucephala</i>	birch	50
14.	<i>Clostera anastomosis</i> *	aspen, willow	10
15.	<i>Zeiraphera rufimitrana</i>	fir	100
16.	<i>Coleophera dahurica</i>	larch	100
17.	<i>Zeiraphera griseana</i>	larch	>1000

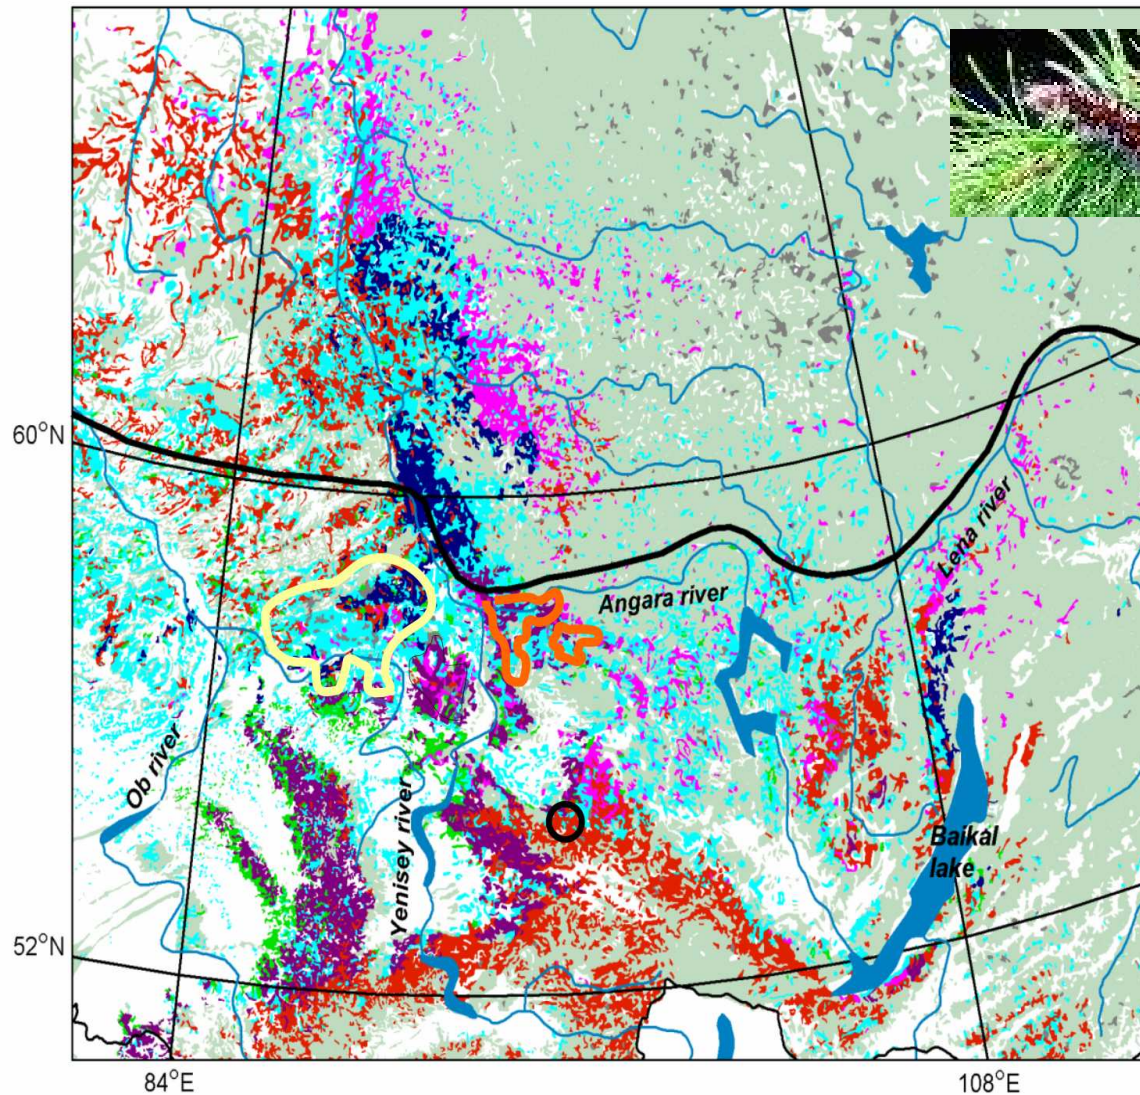

The most dangerous species is the Siberian silkmoth

(*Dendrolimus superans sibiricus* Tschetw.).

This insect causes forest damage and mortality up to **>1 mln ha per outbreak**

The map of actual and potential Siberian silkmoth food base

Outbreak areas:

1 (yellow line) – of 1950s;

2 (red line) - of 1990s,

3 (black circle) - of 21st century;

The temporal trend
in outbreak periodicity
is observing:

25 yr, 25yr, 12 yr, and 8 yr.

Solid line:

northern limit of outbreak zone.

**Under the impact of climate change
this border will shift
northward.**

Secondary pests (bark beetles) attacked stands weakened by Siberian silkmoth

Insect-killed stands becomes a “firewood” for the periodic follow-on fires

The catastrophic scale of outbreaks requires adequate methods of detection and mapping.

The purpose of this study is evaluation of Terra/MODIS and SPOTVegetation data for detection of Siberian silkmoth outbreaks.

zone of Siberian silkmoth outbreak in 1990's.

**The disturbances: pest outbreak, logging, fires
(including outbreak-promoting)**

A landscape: plateau

Insect outbreaks in Central Siberia

outbreak
areas

AVHRR derived and conventional mapping insect damage

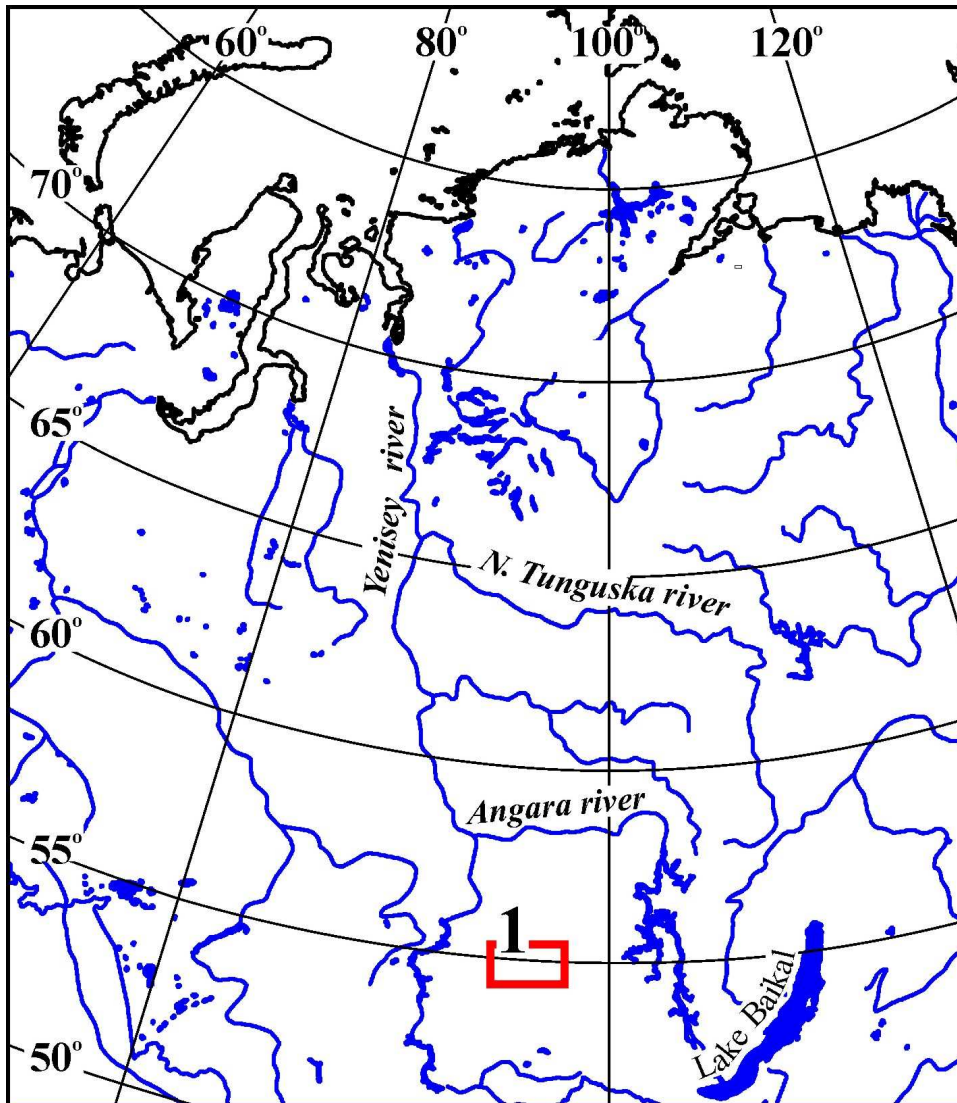

Area of investigations _2:

zone of Siberian silkmoth outbreak in 2000's.

The disturbances: pest outbreak, logging, fires

SPOT Veg Image

A landscape: mountains

1. The outbreak zone.
2. The main outbreak spot.

NDVI difference dynamics between healthy and damaged stands (normalized data)

1 – SPOTVeg
2 – TERRA/MODIS

Damaged stands area dynamics

1 – SPOT-Vegetation; 2 – Terra\MODIS

Is the initial outbreak phase related to landscape features (aspect, slope steepness, and elevation)?

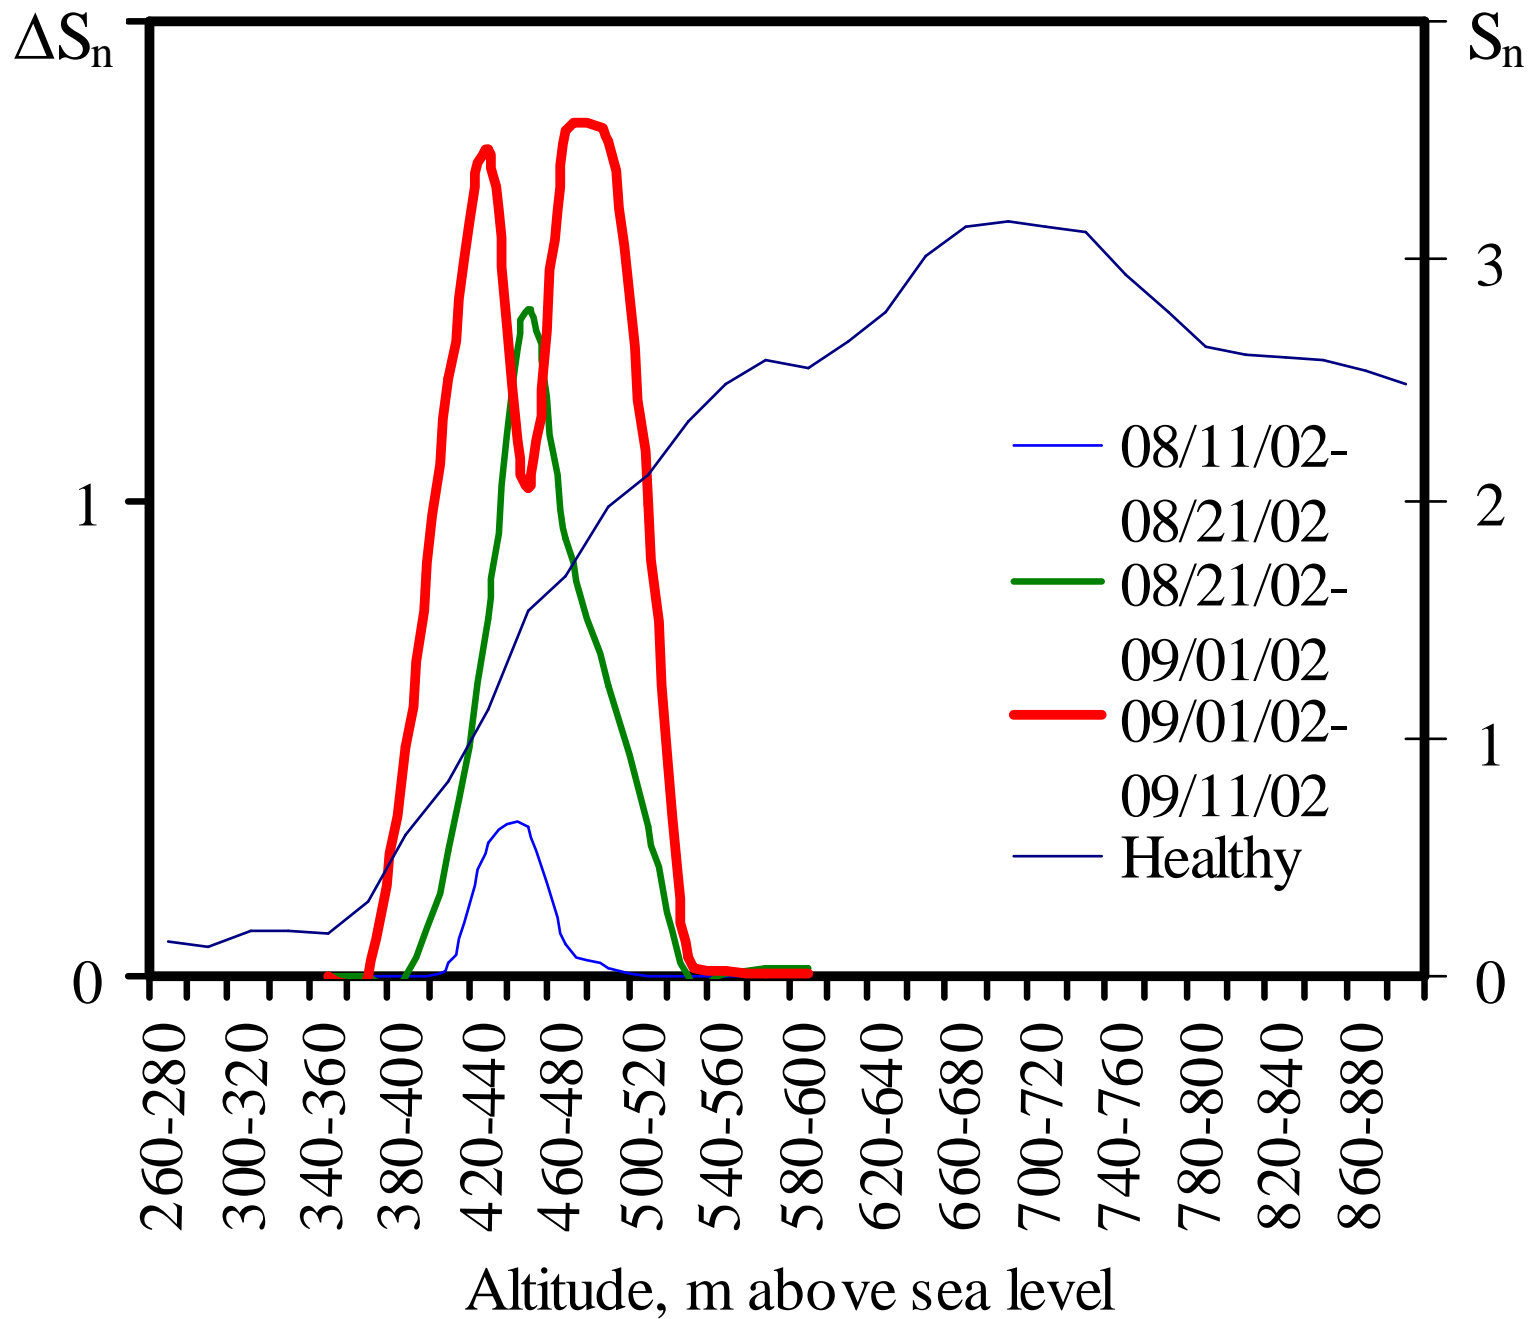

To answer this question, we used high resolution 3D model

Damaged stands area increment dynamics (with respect to aspect)

Damaged stands area
increment dynamics
(with respect to slope
steepness)

Increment dynamics of normalized damaged stands (ΔS_n) with respect to altitude (S_n – normalized area of healthy stands)

3d view (not a map!) on areas damaged pests

Conclusions

1. **SPOT-Veg and Terra/MODIS sensors showed a good accuracy (>90%) for the outbreak area estimation.**
2. **Initial outbreak phase is related to topography features. This may be used for early detection of pest outbreak.**
3. **Mapping of pre- and post-outbreak temporal dynamics is necessary.**
